Hemodynamic cardiovascular models provide non-invasive estimates of important clinical indicators. Although the use of hemodynamic models is increasing, difficulties in quantifying the effects of uncertainty stemming from multiple sources hinders widespread adoption in the clinic. The desire for clinically relevant and useable results motivates the transition to a stochastic framework for uncertainty quantification (UQ). However, in the cardiovascular modeling context, standard approaches for UQ face significant challenges due to the large number of uncertain inputs and the significant computational cost of realistic three-dimensional simulations. We propose a stochastic framework that leverages three cardiovascular model fidelities, with varying temporal and spatial mesh levels, to rigorously quantify the variability in hemodynamic outputs while, at the same time, keeping the computational cost reasonable. Using the SimVascular open-source platform, 3D anatomic models are constructed from medical image data, followed by the solution of incompressible Navier-Stokes equations governing blood flow in elastically deformable vessels [1,2]. Simplifying assumptions generate lower-fidelity models. 1D models consist of a simplified geometry automatically extracted from the 3D model, while 0D models are obtained from equivalent circuit representations of blood flow in deformable vessels. Multi-level and multi-fidelity (MLMF) estimators [3] implemented in Sandia's DAKOTA toolkit are leveraged to reduce the variance in our output quantities of interest (QoIs) while maintaining reasonable computational cost. We demonstrate this framework on healthy and diseased models of aortic and coronary anatomies. We simulate both steady and pulsatile input flow waveforms for all models. Uncertainties in the parameters defining the material properties of the vessels and fluid, as well as the lumped parameter RCR (aortic model) and coronary (coronary model) outlet boundary conditions are investigated after first tuning these parameters to produce realistic output hemodynamic values. The performance of the MLMF estimators is measured by the computational cost to obtain a given accuracy of global and local hemodynamic QoIs as compared to traditional UQ methods. We see significant, on the order of 10 to 100 times, reduction in total computational cost. As expected, global quantities, including pressure and flow waveform properties, show larger reductions with the MLMF estimators than local quantities, such as those relating to wall shear stress, as the latter rely more heavily on the highest fidelity model evaluations. ABSTRACT

This paper aims to analyse the post-cracking behaviour of real scale RC beams made of Fibre-Reinforced concrete (FRC) and tested in four-point-bending. Specifically, it proposes a model based on combining an appropriate fracture-based stress-crack opening relationship for the plain concrete matrix with proper constitutive laws aimed at capturing the crack-bridging effect of macro-fibres. An original meso-scale approach is followed for reproducing the complex influence of fibres on the overall response depending on the cracking onset and evolution. Particularly, explicit mechanisms, such as pull-out and dowel actions [1], are explicitly modelled, taking into account fibre type, geometry and spatial distribution: the presence of different types of fibres in FRC is also covered by the model. Moreover, the mechanical contribution of steel reinforcing bars is also taken into consideration. Numerical analyses demonstrate the accuracy of the proposed model, as their output are in very good agreement with a set of experimental results on RC beams recently tested at the University of Buenos Aires. The theoretical modelling activity presented in this paper stem out of the “SUPERCONCRETE” (H2020-MSCA-RISE-2014 n 645704) project, funded by the European Union as part of the H2020 Framework Programme. ABSTRACT

Errors and uncertainties in finite element method (FEM) computing can come from the following eight sources, the first four being FEM-method-specific, and the second four, model-specific: (1) Computing platform such as ABAQUS, ANSYS, COMSOL, LS-DYNA, etc.; (2) choice of element types in designing a mesh; (3) choice of mean element density or degrees of freedom (DOF) in the same mesh design; (4) choice of a relative percent error (RPE) or the Rate of RPE per DOF on a log-log plot to assure solution convergence; (5) uncertainty in geometric parameters of the model; (6) uncertainty in physical and material property parameters of the model; (7) uncertainty in loading parameters of the model, and (8) uncertainty in the choice of the model. By considering every FEM solution as the result of a numerical experiment for a fixed model, a purely mathematical problem, i.e., solution verification, can be addressed by first quantifying the errors and uncertainties due to the first four of the eight sources listed above, and then developing numerical algorithms and easy-to-use metrics to assess the solution accuracy of all candidate solutions. In this paper, we present a new approach to FEM verification by applying three mathematical methods and formulating three metrics for solution accuracy assessment. The three methods are: (1) A 4-parameter logistic function to find an asymptotic solution of FEM simulations; (2) the nonlinear least squares method in combination with the logistic function to find an estimate of the 95 % confidence bounds of the asymptotic solution; and (3) the definition of the Jacobian of a single finite element in order to compute the Jacobians of all elements in a FEM mesh. Using those three methods, we develop numerical tools to estimate (a) the uncertainty of a FEM solution at one billion DOF, (b) the gain in the rate of RPE per DOE as the asymptotic solution approaches very large DOE's, and (c) the standard deviation of the Jacobian distribution (sd-J) of a given mesh design. Those three quantities are shown to be useful metrics to assess the accuracy of candidate solutions in order to arrive at a so-called "best" estimate with uncertainty quantification. Our results include calibration of those three metrics using problems of known analytical solutions and the application of the metrics to sample prolems, of which no theoretical solution is known to exist. A Goal-Oriented, Inverse Decision-Based Design Computational Framework for the Robust Design of an American Football Helmet

Tate Fonville*, Anand Nellippallil**, Mark Horstemeyer***, Farrokh Mistree****

*Mississippi State University, **University of Oklahoma, ***Mississippi State University, ****University of Oklahoma

ABSTRACT

Much has been written about brain damage to athletes who participate in contact sports in general and American football in particular. Essentially, helmet equipment has not been historically designed with the metrics directly related to the brain. By using brain damage as a performance metric, we are developing a goal-oriented, inverse decision-based design method with the end performance goal of total energy absorption so as to mitigate the possibility of brain damage to athletes. The helmet system is partitioned into three subassemblies, namely, the helmet shell, the stress wave damper, and the helmet liner. In the shell subassembly, thickness of the paint and outer/inner shells are treated as variables. The stress wave damper is fixed to the shell and specifications (for example, base radius, length, volume, etc.) for the complex geometry are treated as variables. The liner subassembly consists of Velcro, TPU foam wrap, and the foam material with thickness and area ratio being treated as variables. Each of the subassemblies is linked via an information chain (consisting of variables and goals) beginning with the paint and ending with the liner foam. Considering the end goal of zero energy at the head, we define the forward process as an energy transfer from the external paint to the helmet liner. We solve for subassembly specifications in an inverse manner beginning with the foam liner and working backwards towards the paint. The mathematics underlying our proposed goal-oriented, inverse decision-based design method is embodied in the Concept Exploration Framework (CEF). We plan to garner the data from finite element analysis using Abaqus (explicit) in which an Internal State Variable (ISV) elastic-viscoplastic material model will be used to accurately capture the constitutive behavior of the helmet shell, the stress wave damper, and the helmet liner. The boundary conditions will include a normal load and a transverse load with velocities appropriated by the NOCSAE standard for American Football Helmets. In keeping with the theme of the conference, namely, Computational Mechanics in Complex Product Development, in our paper we plan to present the salient features a. of the partitioning of a complex design problem (a football helmet); b. of the computational mechanics to support design decision making (modeling the behavior of the helmet shell, the stress wave damper, and the helmet liner); c. of the Concept Exploration Framework.

Extended Finite Elements Applied to Poroelasticity in Faulted Porous Media

Luca Formaggia*, Anna Scottio**, Daqing Liu***

*Politecnico di Milano, **Politecnico di Milano, ***Politecnico di Milano

ABSTRACT

In several applications related, for instance, to the exploitation of oil and geothermal reservoirs and CO2 sequestration activities, the injection or extraction of fluids can alter the stress field in the reservoir and induce preexisting faults to reactivate. Simulation of this type of phenomena requires to couple the poroelastic equations with a model of the hydraulic and mechanical behavior of the fault. In this context, the eXtended Finite Element Method (XFEM) can be of interest to account for discontinuities in the flow and displacement fields. In this work, the fault is defined by a one-codimensional interface and we have implemented the coupling conditions describing the frictional contact by a Nitsche approach. This is an alternative to the augmented Lagrangian formulations more commonly used for this type of problem. A fixed-stress splitting strategy, extended to this type of problem, has been used to decouple the computation of pressure and displacement. Mixed formulation has been used for the flow field, giving rise to a three field formulation. In this presentation we will illustrate some preliminary results of this procedure.

Coupling FEM and Meshfree Peridynamics for Efficient Simulation of Hydraulic Fracturing

John Foster*, Jason York**

*The University of Texas at Austin, **The University of Texas at Austin

ABSTRACT

In the effort to create new technology to enhance our ability to retrieve usable hydrocarbons, the technique of hydraulic fracturing has shown to be extremely beneficial. This involves pumping fluids at high pressures to induce and propagate fractures near the wellbore to stimulate production in otherwise low permeability reservoirs. To better understand the physical processes involved, several models have been proposed for numeric simulation. This work expands on the nonlocal hydraulic fracturing model based on the theory of peridynamics, detailed in Ouchi et al. (2015). As the model continues to develop complex capabilities, such as fully coupled poromechanics and inelasticity, computational expense continues to be an ever-growing concern. In the work by Galvaentto et al. (2016), a method is introduced for coupling nonlocal bond-based peridynamic grids with local finite element meshes. This coupling method demonstrated applicability to static equilibrium problems, while introducing negligible errors in displacements. In this work, the coupling method is implemented with the nonlocal hydraulic fracturing model, using peridynamics near existent and propagating fractures, as well as a standard Galerkin finite element formulation away from fractures. To increase computational efficiency, adaptive meshing techniques are introduced with the capability of converting finite element nodes to meshfree peridynamic nodes. This presentation will include a discussion of the model and techniques implemented, as well as their impact on simulation capabilities and performance. On the Behavior of a Roller Bearing Seismic Isolator

Dora Foti*, Nicola Menga**, Giuseppe Carbone***

*Polytechnic University of Bari, **Polytechnic University of Bari, ***Polytechnic University of Bari

ABSTRACT

Abstract In this paper, we focus on the behavior of an innovative seismic rolling isolator in light to provide a passive protection to light structures from earthquakes damages. The specific isolation system belongs to the class of Rubber Layer Rolling Bearings (RLRB), and consists of steel cylinders interposed between steel plates padded with viscoelastic layers (rubber). Due to the geometry of the RLRB system, a partial motion decoupling is introduced between the ground and the superstructure. Moreover, the high-damping viscoelastic material employed in the system partially dissipate the seismic energy, thus reducing the relative displacement between the base and the building. In this work, we provide a deep insight into the viscoelastic behavior of such a isolation system. We specifically address the contact problem between the rigid cylinders and the viscoelastic layers, exploiting specific contact mechanics techniques to correctly model the effect of the layers finite thickness on the results. The theoretical model provides useful guidelines for a design optimization aiming at producing high energy dissipation with low force transmissibility. Further, in view of an extension to the case of multi-layer rubber system, we investigate the effect of different boundary conditions on the viscoelastic layers involved in the RLRB isolator, such as: (i) a rigid constraint; (ii) a uniformly distributed pressure. These, represent the two limiting cases of a layered system in which the external layer stiffness is infinitely high and vanishing, respectively. References D. Foti, A. Catalan Goni, S. Vacca. On Non-Uniform Torsion in FGM Beam Structures and the Extraction of Relevant Stiffness Quantities based on SAFE

Peter Fotiu*, Justin Murin**, Stephan Kugler***

*University of Applied Sciences Wiener Neustadt, Austria, **Slovak University of Technology in Bratislava, ***University of Applied Sciences Wiener Neustadt, Austria

ABSTRACT

Beam structures made of a Functionally Graded Materials (FGMs) show location dependent material parameters throughout their arbitrarily shaped cross-section. The load case of torsion introduces warping of the cross-section and a non-uniform theory of torsion has to be applied to achieve accurate solutions using one-dimensional finite elements. Starting with a suitable kinematic assumption where the cross-section rotates rigidly in its projection plane pivoting at the shear or drill center, the axial motion of a generic point is quantified based on an unknown warping function (depending on the cross-section coordinates) multiplied with an axial field quantifying the amount of warping. The well-known and frequently applied Vlasov's theory of torsion uses the first derivative of torsion angle phi to quantify warping axially. This leads to two independent stiffness quantities (torsion stiffness and warping stiffness) which have to be identified using SAFE in connection with one fourth order ODE. Such a strategy delivers shear stress distributions due to torsion only and not based on warping. The resultant torsional moment is separated artificially into a primary part (due to torsion) and into a secondary part due to warping. Alternatively, if the axial distribution of warping may be related to a yet unknown independent field rather than to the rate of twist, resulting in two coupled second order ODEs and four stiffness quantities. Such a calculation strategy is similar to the rarely applied Benscoter theory of torsion and does not require any artificial separation of section resultants since the shear stress distributions are related to both torsion and warping. Additionally, it can be shown by example that this theory of warping torsion leads to more accurate results in relation to three dimensional continuum solutions compared to Vlasov's theory especially for thick shafts. While analytical evaluations regarding a set of two coupled ODEs are somewhat more involved very efficient finite beam elements can be derived based on linear shape functions. The evaluations of the related stiffness quantities can be carried out using a reference beam problem of arbitrary length in connection with three dimensional elasticity solutions where semi-analytical finite elements (SAFE) are applied. Due to SAFE and a specialized load case for the reference problem a true dimension reduction is achieved and stress distributions, relevant cross-section parameters and stiffness quantities are accessible based on discretization of the cross-section only.

ABSTRACT

The adoption of tetrahedral elements in solid mechanics hinges on field resolution under finite deformations, inelasticity, contact, and transient dynamics. In this work, we present new developments in a recently reformulated, 10-node composite tetrahedral element [1]. We specifically illustrate a new integration scheme for the gradient operator that accounts for curved or “kinked” edges in which the mid-edge node is not located at the midpoint of adjacent, parent nodes. In addition, we also develop a new methodology for the stress projection and the rendering of the forces. Examples of increasing complexity in both quasi-statics and explicit transient dynamics will attempt to illustrate the benefits of the new formulation in the context of a larger workflow to reduce the time from design to analysis. ABSTRACT

Since the work of Fung (see reference 1) there has been a clear need of new generation models capable to bridge together the scales at which multiphysics phenomena govern growth and remodeling of biological tissues. In this work, the authors propose an experimentally informed multiscale methodology based on Structured Deformations (see reference 2), delivering effective fields characterizing the geometrical changes of bodies at multiple scales. Structured Deformations intrinsically can account for microstructural changes at various length scales, including formation and coalescence of voids and rearrangements of the material. Unlike traditional, yet phenomenological, local multiplicative decomposition of the deformation gradient widely used in growing media, the fields arising in Structured Deformations allow for describing the kinematics of the whole body, including both growth and remodeling. This arises through precise bottom-up characterizations, owing the submacroscopic structure of the material to bear trace macroscopically. In order to extract effective constitutive properties of tissues undergoing growth and remodeling, a novel multiscale targeted bottom-up approach is proposed to find the (Helmholtz) energetics governing the multiphysics involved in such processes. The approach can be relevant to follow structural and morphological reorganization of a number of biological tissues where growth and remodeling are crucial issues and could be easily coupled with cells competition occurring at micro-scale level to include selected bio-chemical dynamics (see reference 3). 1) Y.C. ABSTRACT

The aim of the talk is to present a purely Lagrangian method to simulate free-surface Bingham fluids and their interaction with structures, also accounting for the 3D effects. The Particle Finite Element Method (PFEM) [1] is used to deal with bodies that are suffering from huge deformations. A Papanastasiou model has been implemented into a stabilized PFEM strategy [2] with the aim of modeling both Newtonian and Non-Newtonian fluid flows. The possibility of coupling the PFEM model with a Discrete Element Method (DEM) formulation is also investigated. On the other hand, to compute the solid objects and structures that interact with the fluid flow, the standard Finite Element Method (FEM) and a hypoelastic constitutive model are used. The fluid-solid coupling is modeled via a monolithic approach for fluid-structure interaction (FSI), called Unified formulation [3]. Several 2D and 3D numerical examples are presented. The numerical tests include the simulation of fresh concrete slump tests, a mud flow over an inclined plane receiving the impact of a solid object, and dam break of Bingham fluids against an elastic membrane. The numerical simulations are validated against the results of laboratory tests or those available in the literature. [1] S.R. Idelsohn, E. Oñate, and F. Del Pin. ABSTRACT

Modeling highly impulsive extreme loading events is of significant interest to government, industry, and academia. Some areas of U.S. Army interest include the study of events like projectile penetration, shaped-charge penetration, and close-in explosive detonation, which involve a spectrum of challenging material behaviors and failure modes. Material behaviors resulting from the high-rate impulsive loading, large deformations and material damage, fracture, and failure must be accurately represented; accurate representation of material geometry and interfaces is also essential. Other key elements include capturing material compressibility in the high pressure environment and the damping of different materials under explosive loading. Lagrangian hydrocodes are preferred for simulation of structural response dominated events, but this presents additional challenges with computational cost for some embedded detonation problems where the spatial and temporal domains can be very large. The ability to accurately model these essential mechanisms of embedded detonation problems pose challenges from the perspectives of 1) developing efficient and effective material models that go beyond basic phenomenological formulations, and 2) experimental characterization to accurately quantify the material response and subsequently enable model enhancement. The U.S. Army Engineer Research and Development Center (ERDC) has specific interests in this class of problems and in tools for modeling embedded detonation effects. Accordingly, ERDC has developed constitutive models to work towards developing improved capabilities that address these geomaterial response modeling challenges [1,2]. These models are three-invariant plasticity models that simulate non-linear elastic behavior, irreversible hydrostatic crushing, material yielding, plastic flow, and damage. They contain unique features to simulate the rate-dependent response of geomaterials, including rate-dependent behavior in cohesive strength, frictional strength, hydrostatic crushing, and material damage. Here we will provide an overview of the models and include benchmark experiments used in model validation. Example simulations of embedded detonations in layered geomaterials and the material failure mechanisms produced will also be discussed. REFERENCES [1] A.O. *Institute of Mechanics, Karlsruhe Institute of Technology (KIT), Germany, **Institute of Mechanics, Karlsruhe Institute of Technology (KIT), Germany, ***Zienkiewicz Centre for Computational Engineering, Zienkiewicz Centre for Computational Engineering, ****Institute of Mechanics, Karlsruhe Institute of Technology (KIT), Germany, *****Institute of Mechanics, Karlsruhe Institute of Technology (KIT), Germany

ABSTRACT

A new approach for the design of energy-momentum (EM) consistent time integrators for nonlinear coupled problems is proposed. Polyconvexity inspired internal or Helmholtz free energy functionals are obtained by using the rediscovered tensor cross product which is basically applied on the cofactor and the Jacobian of the right Cauchy-Green strain tensor and greatly simplifies the algebra, see Betsch, Janz and Hesch (submitted to Comput. Methods Appl. Mech. Engrg., 2017). On this basis multi-field problems concerning non-linear thermo-elastodynamics, see Franke, Janz, Schiebl, Betsch (submitted to Int. J. Numer. Meth. Engng., 2017) and electro-elastodynamics, see Ortigosa, Franke, Janz, Gil and Betsch (submitted to Comput. Methods Appl. Mech. Engrg., 2017), are considered. For the former a temperature based weak form is employed which facilitates the design of a structure-preserving time-stepping scheme for coupled thermo-elastic problems. For the latter a three-field internal energy-based formulation is applied. In both cases, the polyconvexity-based framework facilitates the design of EM consistent time integrators. In particular algorithmic stress formulas are employed which show a remarkably simple structure when compared to traditional, elaborate projection-based formulas. The spatial discretization relies on finite element interpolations for the unknown fields. Eventually, the superior performance of the proposed formulations is shown in several numerical examples.

Inverse Problem Coupled with the Genetic Algorithm Procedure in Modeling of Biomaterials Behavior

Marina Franulovic*, Kristina Markovic**, Stjepan Pilicic***

*Faculty of Engineering, University of Rijeka, **Faculty of Engineering, University of Rijeka, ***Faculty of Engineering, University of Rijeka

ABSTRACT

Modeling of material behavior and consequently its simulation in the operating conditions is an important step in understanding the consequences of the loading impact on various systems. This refers to the material behavior of different conventional and synthetic materials with the application on the assembly constituents' mechanical design, but also on biomaterials modeling for the simulation of the biomechanical systems. The biomaterials behavior modeling is based on the recorded stretch-stress response of the specimens isolated from the biomechanical test subjects and experimented on, together with the chosen material model appropriate for description of the phenomena that appear in material during loading. In order to make possible inverse modeling in the process of material behavior simulation, the definition of physical interdependence among unknown variables, here known as material parameters, and material response during loading, is necessary. The data sets acquired from the experimental procedures represent the probing signal for the inverse setup in the material parameter identification process. The inverse modeling here is coupled with the genetic algorithm procedure to make possible fast convergence to as accurate as possible results in presented highly non-linear material behavior. Genetic algorithm procedure has thus been developed here to identify parameters for the behavior modeling of ligaments of the human cervical spine. The procedure consists of three main parts: system characterization where influential parameters are defined, forward modeling where mechanical principles are proposed and inverse or backward modeling where objective function for the problem is set. The material characterization based on coupling inverse problem within the genetic algorithm procedure has so far proved to be applicable for parameters identification of materials with different microstructure and mechanical properties. Since it exhibited flexibility and robustness, besides for the modeling of the biomaterials, it might also be applicable to behavior characterization of other non-conventional and innovative materials. This work has been supported by Croatian Science Foundation under the project number IP-2014-09-4982 and also by the University of Rijeka under the projects number (13.09.1.2.09) and(13.09.2.2.18).

Meshfree Contact Algorithm with Provisions for Solid State Joining – Application to the Additive Friction Stir Process

Kirk Fraser*, George Stubblefield**, Robert Escobar***, Paul Allison****, Brian Jordon*****

*National Research Council Canada, **University of Alabama, ***University of Alabama, ****University of Alabama, *****University of Alabama

ABSTRACT

The additive friction stir (AFS) process is a new additive manufacturing (AM) approach where a consumable probe is deposited onto a work piece using a friction stir tool. The probe is pushed through a hole in the tool, friction between the tool/probe and the work piece causes heat to be generated. The deposited probe material forms a solid-state bond with the work piece, leading to excellent mechanical properties of the AM part. Certainly, AFS shows great promise as a high value AM process. However, significant efforts to understand better the process will be needed in the near future. Various parameters such as tool rpm, advancing speed, and probe federate (to name a few) need to be selected to have good quality AM parts. To facilitate this task, a meshfree coupled thermo-mechanical simulation code, SPHriction-3D [1], can be used. The code is ideally suited for the simulation of large plastic deformation processes such as AFS. An advanced parallelization scheme is employed on the GPU, which permits robust and efficient calculations for complex multi-physics problems in a reasonable time frame. In this work, a new meshfree joining contact algorithm is developed to take into account the intricate interaction of the work piece and the consumable probe material. Initially, the meshfree material points used to discretize the probe and the work piece are treated as two distinct and separate entities. At this point, their interactions are through a penalty based thermo-mechanical contact algorithm. Once a material point at the work piece/probe interface attains a threshold energy level, the material point is considered to be joined and interacts through the meshfree kernel. The new contact algorithm allows the SPHriction-3D code to simulate aspects of the AFS process such as material deposition, heat generation, work piece/probe mixing, as well as defect prediction. Optimization with Polymorphic Uncertainty Models for the Design of Durable Reinforced Concrete Structures

Steffen Freitag*, Philipp Edler**, Katharina Kremer***, Günther Meschke****

*Ruhr University Bochum, **Ruhr University Bochum, ***Ruhr University Bochum, ****Ruhr University Bochum

ABSTRACT

The lifetime oriented design of reinforced concrete (RC) structures requires to consider the expected service loads and the long-term behavior of RC. The durability of RC structures is dominated by steel reinforcement corrosion, which is driven by load induced cracking and the transport of corrosive substances into the structure. The crack width at the reinforcement layers is manly influencing the lifetime of RC structures. In addition to a precise physical modelling of the structural behavior, it is also important to consider uncertainties of the structural loading and the material resistance within the design process. Here, finite element models are applied together with polymorphic uncertainty models within an optimization approach to improve the design of RC structures with respect to durability. In contrast to pure stochastic models, where all uncertain parameters are described by stochastic distributions, polymorphic uncertainty models allow to consider both, aleatoric and epistemic sources of uncertainty by combining stochastic and non-stochastic approaches such as intervals and fuzzy numbers. Within an optimization problem, polymorphic uncertain parameters can either be a priori parameters or design parameters to be optimized. In both cases, a surrogate problem has to be formulated to solve the optimization task, e.g. minimizing mean values, variances or quantile values in case of stochastic a priori or design parameters and e.g. worst case optimization in case of interval a priori or design parameters. To consider polymorphic uncertain design and a priori parameters, existing optimization strategies, such as the particle swarm optimization approach, are extended and modified in a way, that Monte-Carlo simulations are performed together with and interval analyses for each realization of the design parameters. The new optimization strategies are applied to optimize the reinforcement layout (number and diameter of reinforcement bars and the corresponding concrete cover) of an RC bridge structure. Whereas the number and diameter of the reinforcement bars are discrete deterministic design parameters, the concrete covers are modeled as interval design parameters, with midpoints to be optimized and given radiuses taking construction imprecisions into account. The service load and the most sensitive concrete material parameters are considered as stochastic a priori parameters within the optimization. The mean value and variance of the crack width at the reinforcement layer are used as optimization objective to be minimized and the structural reliability is treated as a constraint in terms of the accepted failure probability with respect to the load bearing capacity.

Error Modeling for Approximate Solutions to Parameterized Systems of Nonlinear Equations Using Machine Learning

Brian Freno*, Kevin Carlberg**

*Sandia National Laboratories, **Sandia National Laboratories

ABSTRACT

Decision-making applications in computational science and engineering typically require repeated evaluations of a parameterized model. Often, these models consist of nonlinear partial differential equations that are cast algebraically. For large-scale models, the computational cost associated with this many-query setting is prohibitive; therefore, solutions approximations must be employed for tractability. Examples of solutions approximations include those that arise from reduced-order models, coarse-mesh solutions, and unconverged iterations. While such approximations reduce the computational burden, often by orders of magnitude, they incur error with respect to the high-fidelity model that should be accounted for in the ultimate decision-making application. We present an approach to quantify the error introduced by these solution approximations. This is accomplished by (1) engineering features that are informative of the error, and (2) applying machine learning regression techniques (e.g., artificial neural networks, random forests, support vector machines) to construct a statistical model of the error from these features. We consider both (signed) errors in quantities of interest, as well as global state-space error norms. We present several examples to demonstrate the effectiveness of the proposed approach compared to more conventional feature and regression choices. In each of the examples, including a problem characterized by more than a quarter million degrees of freedom, the predicted errors have a coefficient of determination (R squared) value of at least 0.998.

A Kinematic Evolution Equation for the Dynamic Contact Angle and some Consequences

Mathis Fricke*, Dieter Bothe**, Matthias Köhne***

*TU Darmstadt, Germany, **TU Darmstadt, Germany, ***HHU Düsseldorf, Germany

ABSTRACT

We address the moving contact line problem for two-phase incompressible flows by a kinematic (or geometrical) approach. The key idea is to derive an evolution equation for the contact angle if the transporting velocity field is given. It turns out that the resulting equation has a simple structure and expresses the time derivative of the contact angle in terms of the gradient of the velocity field at the solid wall. This result can be used to test the ability of a numerical method to correctly transport the contact angle. The imposed boundary conditions provide some information about the velocity gradient. Using this information, the kinematic evolution equation is a tool to analyze the contact angle evolution. In this paper we consider the Navier slip boundary condition, which is frequently used for the modeling of moving contact lines. Exploiting the interfacial transmission condition for the viscous stress, we derive an explicit form of the contact angle evolution for a large class of models which only involves the contact line velocity and the slip length from the Navier condition. From this equation we can read off the qualitative behavior of the contact angle evolution for smooth solutions to this class of models, which turns out to be unphysical. In particular, if the contact angle is directly related to the contact line velocity, the contact angle is a monotonically increasing or decreasing function. We discuss consequences from this observation, possible generalizations of the model as well as implications for numerical methods. ACKNOWLEDGEMENTS We kindly acknowledge the financial support by the German Research Foundation (DFG) within the Collaborative Research Centre 1194 “Interaction of Transport and Wetting Processes”, Project B01.

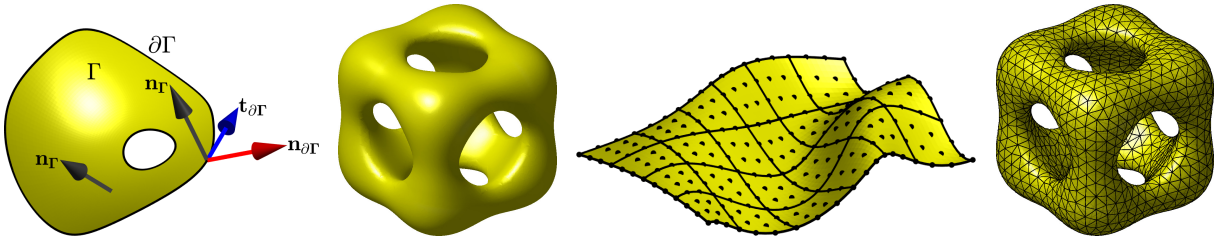
Key words: Stokes, Navier-Stokes, higher-order FEM, surface FEM, surface PDEs, manifold

Abstract. A mixed, stabilized, higher-order accurate surface finite element method is considered for stationary and instationary Stokes and Navier-Stokes flows on curved, two-dimensional manifolds. Individual element orders are employed for the velocities, pressure, and Lagrange multiplier to enforce tangential velocities. Stream-line upwind stabilization is used for flows at high Reynolds numbers. Numerical test cases are proposed and higher-order convergence rates confirmed.

1 INTRODUCTION

Flows on curved surfaces in three dimensions are important in transport processes on interfaces, e.g., in foams, biomembranes and bubble surfaces. Models for incompressible flows on two-dimensional manifolds are found, e.g., in [1–4]. Herein, the surface FEM [5–7] is employed for the approximation of stationary and instationary (Navier-)Stokes flows on general, yet fix surfaces. The involved fields are approximated using different orders of the shape functions, namely for the velocities, pressure, and Lagrange multiplier to enforce tangential velocities. The well-known Babuška-Brezzi condition applies for the resulting mixed FEM [8,9]. Streamline-upwind Petrov-Galerkin (SUPG) stabilization is recommended for Navier-Stokes flows at large Reynolds numbers [10,11]. For the case of the instationary Navier-Stokes equations, the Crank-Nicolson time stepping scheme is employed for the semi-discrete sytem of equations resulting from using the surface FEM in space. This work is a revision of [12,13] proposing new test cases. The numerical results show that higher-order convergence rates are achieved provided that the finite element spaces are properly chosen.

The paper is organized as follows: In Section 2, the governing equations for (i) Stokes flow, (ii) stationary, and (iii) instationary Navier-Stokes flows on two-dimensional manifolds are given in strong form and weak form according to the surface FEM. Numerical results are



(a) (b) (c) (d)

Figure 1: (a) Generic surface with normal and tangential vectors, (b) compact surface, (c) and (d) surface meshes.

presented in Section 3 and confirm higher-order accuracy. Finally, conclusions are given in Section 4.

2 GOVERNING EQUATIONS

A curved, smooth, orientable, connected surface Γ which is fixed in space over time and features a finite area is considered. There is a unit normal vector $\boldsymbol{n}_\Gamma \in \mathbb{R}^3$ on Γ. The surface may feature a boundary $\partial\Gamma$ with tangential vector $\boldsymbol{t}_{\partial\Gamma}$ pointing in direction of $\partial\Gamma$ and a co-normal vector $\boldsymbol{n}_{\partial\Gamma} = \boldsymbol{n}_\Gamma \times \boldsymbol{t}_{\partial\Gamma}$, see Fig. 1(a). The surface may also be compact, then, $\partial\Gamma = \emptyset$, see Fig. 1(b) and it may be given in parametrized form or implied, e.g., based on the level-set method. For the equivalence of these two cases and more mathematical details, see, e.g.,[7]. The manifold is discretized by suitable meshes of different orders and types (triangular or quadrilateral elements), see Figs. 1(c) and (d).

2.1 Surface gradients and divergence

On the manifold Γ, the tangential projector $\mathbf{P}(\boldsymbol{x}) \in \mathbb{R}^{3\times3}$ is defined by the normal vector as

$$\mathbf{P}(\boldsymbol{x}) = \mathbf{I} - \boldsymbol{n}_\Gamma(\boldsymbol{x}) \otimes \boldsymbol{n}_\Gamma(\boldsymbol{x}).$$

with $\mathbf{P}\cdot\boldsymbol{n}_\Gamma = \mathbf{0}$, $\mathbf{P} = \mathbf{P}^{\mathrm{T}}$, and $\mathbf{P}\cdot\mathbf{P} = \mathbf{P}$.

The tangential gradient operator ∇_Γ of a differentiable *scalar* function $u : \Gamma \to \mathbb{R}$ on the manifold is given by

$$\nabla_\Gamma u(\boldsymbol{x}) \;=\; \mathbf{P}(\boldsymbol{x}) \cdot \nabla\tilde{u}(\boldsymbol{x}), \quad \boldsymbol{x} \in \Gamma, \tag{1}$$

where ∇ is the standard gradient operator, and $\tilde{u}$ is a smooth extension of u in a neighborhood $\mathcal{U}$ of the manifold Γ. For parametrized surfaces defined by the map $\boldsymbol{x}(\boldsymbol{r}) : \mathbb{R}^2 \to \mathbb{R}^3$, and a given scalar function $u(\boldsymbol{r}) : \mathbb{R}^2 \to \mathbb{R}$, the tangential gradient may be determined without explicitly computing an extension $\tilde{u}$ using

$$\nabla_\Gamma u(\boldsymbol{x}(\boldsymbol{r})) = \mathbf{J}(\boldsymbol{r}) \cdot \mathbf{G}^{-1}(\boldsymbol{r}) \cdot \nabla_{\boldsymbol{r}} u(\boldsymbol{r}), \tag{2}$$

with $\mathbf{J} = {}^{\partial \boldsymbol{x}}/_{\partial \boldsymbol{r}}$ being the (3×2)-Jacobi matrix and $\mathbf{G} = \mathbf{J}^T \cdot \mathbf{J}$ being the metric tensor (first fundamental form). This is relevant in the context of the surface FEM, where $u(\boldsymbol{r})$ are the shape functions in the reference element and tangential gradients are to be determined in the physical surface elements. It is noteworthy that $\nabla_\Gamma u$ is in the tangent space of Γ and, thus, $\mathbf{P} \cdot \nabla_\Gamma u = \nabla_\Gamma u$ and $\nabla_\Gamma u \cdot \boldsymbol{n}_\Gamma = 0$. It is straightforward to determine second order derivatives of scalar functions, see, e.g.,[14]. This is important here in the context of stabilization terms in the governing equations.

When surface gradients of *vector* functions $\boldsymbol{u}(\boldsymbol{x}) : \Gamma \to \mathbb{R}^3$ are considered, it is important to distinguish directional and covariant gradients:

$$\begin{aligned} \nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u}(\boldsymbol{x}) &= \nabla_\Gamma^{\mathrm{dir}} \begin{bmatrix} u(\boldsymbol{x}) \\ v(\boldsymbol{x}) \\ w(\boldsymbol{x}) \end{bmatrix} = \begin{bmatrix} \left(\nabla_\Gamma^{\mathrm{dir}} u\right)^{\mathrm{T}} \\ \left(\nabla_\Gamma^{\mathrm{dir}} v\right)^{\mathrm{T}} \\ \left(\nabla_\Gamma^{\mathrm{dir}} w\right)^{\mathrm{T}} \end{bmatrix} = \nabla \tilde{\boldsymbol{u}} \cdot \mathbf{P}, \\ \nabla_\Gamma^{\mathrm{cov}} \boldsymbol{u}(\boldsymbol{x}) &= \mathbf{P} \cdot \nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u}(\boldsymbol{x}) = \mathbf{P} \cdot \nabla \tilde{\boldsymbol{u}} \cdot \mathbf{P}. \end{aligned}$$

Concerning the surface divergence of vector functions $\boldsymbol{u}(\boldsymbol{x}) : \Gamma \to \mathbb{R}^3$ and tensor functions $\mathbf{A}(\boldsymbol{x}) : \Gamma \to \mathbb{R}^{3\times 3}$, there holds

$$\begin{aligned} \mathrm{div}_\Gamma \boldsymbol{u}(\boldsymbol{x}) &= \mathrm{tr}\left(\nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u}\right) = \mathrm{tr}\left(\nabla_\Gamma^{\mathrm{cov}} \boldsymbol{u}\right) =: \nabla_\Gamma \cdot \boldsymbol{u}, \\ \mathrm{div}_\Gamma \mathbf{A}(\boldsymbol{x}) &= \begin{bmatrix} \mathrm{div}_\Gamma(A_{11}, A_{12}, A_{13}) \\ \mathrm{div}_\Gamma(A_{21}, A_{22}, A_{23}) \\ \mathrm{div}_\Gamma(A_{31}, A_{32}, A_{33}) \end{bmatrix} =: \nabla_\Gamma \cdot \mathbf{A}. \end{aligned}$$

To derive the weak form of the governing equations, the following divergence theorem on manifolds is needed[14,15],

$$\int_\Gamma \boldsymbol{u} \cdot \mathrm{div}_\Gamma \mathbf{A} \, \mathrm{d}A = -\int_\Gamma \nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u} : \mathbf{A} \, \mathrm{d}A + \int_\Gamma \varkappa \cdot \boldsymbol{u} \cdot \mathbf{A} \cdot \boldsymbol{n}_\Gamma \, \mathrm{d}A + \int_{\partial\Gamma} \boldsymbol{u} \cdot \mathbf{A} \cdot \boldsymbol{n}_{\partial\Gamma} \, \mathrm{d}s, \qquad (3)$$

where $\nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u} : \mathbf{A} = \mathrm{tr}\left(\nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u} \cdot \mathbf{A}^{\mathrm{T}}\right)$. For *tangential* tensor functions with $\mathbf{A} = \mathbf{P} \cdot \mathbf{A} \cdot \mathbf{P}$, the term involving the curvature $\varkappa$ vanishes and one finds $\nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u} : \mathbf{A} = \nabla_\Gamma^{\mathrm{cov}} \boldsymbol{u} : \mathbf{A}$.

2.2 Flow models in strong forms

The governing equations for incompressible flows on manifolds are found, e.g., in [1–3] among others. The outline here closely follows [12].

2.2.1 Stationary Stokes flow

Stationary Stokes flow on a manifold is considered first. Let $\boldsymbol{u}(\boldsymbol{x}) \in C^2(\Gamma)$ be the three-dimensional velocity field on the surface Γ, $p(\boldsymbol{x}) \in C^1(\Gamma)$ a pressure field, and $\boldsymbol{f}_t(\boldsymbol{x})$ a tan-

gential body force. The governing field equations to be fulfilled $\forall \boldsymbol{x} \in \Gamma$ are

$$-\mathbf{P} \cdot \operatorname{div}_\Gamma \boldsymbol{\sigma}(\boldsymbol{u}, p) = \boldsymbol{f}_t, \tag{4}$$

$$\operatorname{div}_\Gamma \boldsymbol{u} = 0, \tag{5}$$

$$\boldsymbol{u} \cdot \boldsymbol{n}_\Gamma = 0. \tag{6}$$

Equation (4) expands to three momentum equations, equation (5) is the incompressibility constraint and equation (6) represents the tangential velocity constraint that restricts the velocities to the tangent space of Γ. Two different strain tensors are introduced,

$$\boldsymbol{\varepsilon}^{\mathrm{dir}}(\boldsymbol{u}) = \frac{1}{2} \cdot \left(\nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u} + \left(\nabla_\Gamma^{\mathrm{dir}} \boldsymbol{u} \right)^{\mathrm{T}} \right), \quad \boldsymbol{\varepsilon}^{\mathrm{cov}}(\boldsymbol{u}) = \frac{1}{2} \cdot \left(\nabla_\Gamma^{\mathrm{cov}} \boldsymbol{u} + \left(\nabla_\Gamma^{\mathrm{cov}} \boldsymbol{u} \right)^{\mathrm{T}} \right),$$

which are related to each other as $\boldsymbol{\varepsilon}^{\mathrm{cov}}(\boldsymbol{u}) = \mathbf{P} \cdot \boldsymbol{\varepsilon}^{\mathrm{dir}}(\boldsymbol{u}) \cdot \mathbf{P}$. The stress tensor is then defined as

$$\boldsymbol{\sigma}(\boldsymbol{u}, p) = -p \cdot \mathbf{P} + 2\mu \cdot \boldsymbol{\varepsilon}^{\mathrm{cov}}(\boldsymbol{u})$$

where $\mu \in \mathbb{R}^+$ is the (constant) dynamic viscosity. Dirichlet and Neumann boundary conditions on $\partial\Gamma_{\mathrm{D}}$ and $\partial\Gamma_{\mathrm{N}}$, respectively, are a straightforward extension from the flat case and are omitted here for brevity.

2.2.2 Stationary Navier-Stokes flow

For stationary *Navier-Stokes* flow, a non-linear advection term is added to equation (4) resulting into

$$\varrho \cdot \left(\boldsymbol{u} \cdot \nabla_\Gamma^{\mathrm{cov}} \right) \boldsymbol{u} - \mathbf{P} \cdot \operatorname{div}_\Gamma \boldsymbol{\sigma}(\boldsymbol{x}) = \boldsymbol{f}_t(\boldsymbol{x}), \tag{7}$$

where $\varrho \in \mathbb{R}^+$ is the (constant) fluid density and $\left(\boldsymbol{u} \cdot \nabla_\Gamma^{\mathrm{cov}} \right) \boldsymbol{u} \coloneqq \left(\nabla_\Gamma^{\mathrm{cov}} \boldsymbol{u} \right) \cdot \boldsymbol{u}$. One may also write the body force as $\boldsymbol{f}_t(\boldsymbol{x}) = \varrho \cdot \boldsymbol{g}_t(\boldsymbol{x})$ where $\boldsymbol{g}_t$ may, e.g., consider gravity. The remaining equations (5) and (6) and the boundary conditions remain unchanged.

2.2.3 Instationary Navier-Stokes flow

For *instationary* Navier-Stokes flow, the momentum equation (4) changes to

$$\varrho \cdot \left(\partial_t \boldsymbol{u}(\boldsymbol{x}, t) + \left(\boldsymbol{u} \cdot \nabla_\Gamma^{\mathrm{cov}} \right) \boldsymbol{u} - \boldsymbol{g}_t(\boldsymbol{x}, t) \right) - \mathbf{P} \cdot \operatorname{div}_\Gamma \boldsymbol{\sigma}(\boldsymbol{x}, t) = \mathbf{0}. \tag{8}$$

The functions representing the physical fields live in space (on Γ) *and* time, i.e., in the time interval $\tau = [0, T]$. Therefore, Eqs. (8), (5), and (6) have to be solved in the space-time domain $\Gamma \times \tau$. Herein, we restrict ourselves to spatially fixed manifolds Γ. The boundary conditions also extend in time dimension. Furthermore, an initial condition $\boldsymbol{u}_0(\boldsymbol{x}) = \boldsymbol{u}(\boldsymbol{x}, 0)$ is needed, which fulfills $\operatorname{div}_\Gamma \boldsymbol{u}_0 = 0$ and $\boldsymbol{u}_0 \cdot \boldsymbol{n}_\Gamma = 0$.

2.3 Flow models in weak forms

The standard procedure to obtain weak forms of the governing equations from above is applied: Suitable test and trial function spaces are introduced, the equations in strong form are multiplied by test functions and the divergence theorem on manifolds is applied. It is noted that the surface FEM is used for the discretization of the weak forms. A mixed FEM is used where individual orders for the geometry, k_{geom}, the velocities, $k_{\boldsymbol{u}}$, the pressure, k_p, and the Lagrange multiplier for enforcing the tangential velocity constraint, k_λ, are employed. All shape functions are mapped to the same geometry mesh defining the discrete manifold Γ^h. All quantities introduced above such as the normal vector, projector, and surface operators now refer to Γ^h rather than Γ.

Assume the following suitable discrete test and trial function spaces, resp.,

$$\mathcal{S}_{\boldsymbol{u}}^h = \left\{ \boldsymbol{u}^h \in \left[\mathcal{Q}_{k_{\boldsymbol{u}}}^h\right]^3,\ \boldsymbol{u}^h = \hat{\boldsymbol{u}}^h \text{ on } \partial\Gamma_{\text{D}}^h \right\}, \tag{9}$$

$$\mathcal{V}_{\boldsymbol{u}}^h = \left\{ \boldsymbol{w}_{\boldsymbol{u}}^h \in \left[\mathcal{Q}_{k_{\boldsymbol{u}}}^h\right]^3,\ \boldsymbol{w}_{\boldsymbol{u}}^h = \boldsymbol{0} \text{ on } \partial\Gamma_{\text{D}}^h \right\}, \tag{10}$$

$$\mathcal{S}_p^h = \mathcal{V}_p^h = \mathcal{Q}_{k_p}^h, \tag{11}$$

$$\mathcal{S}_\lambda^h = \mathcal{V}_\lambda^h = \mathcal{Q}_{k_\lambda}^h. \tag{12}$$

$\mathcal{Q}_k^h$ is a general finite element space of order k, i.e., the set of k-th order shape functions mapped to the geometry mesh.

2.3.1 Stationary Stokes flow

The discrete weak form of the Stokes problem reads: Given viscosity $\mu \in \mathbb{R}^+$, body force $\boldsymbol{f}^h(\boldsymbol{x})$ in Γ^h, and traction $\hat{\boldsymbol{t}}^h(\boldsymbol{x})$ on $\partial\Gamma_{\text{N}}^h$, find the velocity field $\boldsymbol{u}^h(\boldsymbol{x}) \in \mathcal{S}_{\boldsymbol{u}}^h$, pressure field $p^h(\boldsymbol{x}) \in \mathcal{S}_p^h$, and Lagrange multiplier field $\lambda^h(\boldsymbol{x}) \in \mathcal{S}_\lambda^h$ such that for all test functions $\left(\boldsymbol{w}_{\boldsymbol{u}}^h, w_p^h, w_\lambda^h\right) \in \mathcal{V}_{\boldsymbol{u}}^h \times \mathcal{V}_p^h \times \mathcal{V}_\lambda^h$, there holds in Γ^h

$$\int_\Gamma \nabla_\Gamma^{\text{dir}} \boldsymbol{w}_{\boldsymbol{u}}^h : \boldsymbol{\sigma}\left(\boldsymbol{u}^h, p^h\right) \mathrm{d}A + \int_\Gamma \lambda^h \cdot \left(\boldsymbol{w}_{\boldsymbol{u}}^h \cdot \boldsymbol{n}_\Gamma^h\right) \mathrm{d}A = \int_\Gamma \boldsymbol{w}_{\boldsymbol{u}}^h \cdot \boldsymbol{f}^h \mathrm{d}A + \int_{\partial\Gamma_{\text{N}}} \boldsymbol{w}_{\boldsymbol{u}}^h \cdot \hat{\boldsymbol{t}}^h \,\mathrm{d}s, \tag{13}$$

$$\int_\Gamma w_p^h \cdot \operatorname{div}_\Gamma \boldsymbol{u}^h \,\mathrm{d}A = 0, \tag{14}$$

$$\int_\Gamma w_\lambda^h \cdot \left(\boldsymbol{u}^h \cdot \boldsymbol{n}_\Gamma^h\right) \mathrm{d}A = 0. \tag{15}$$

The usual element assembly yields a linear system of equations with a saddle point structure as expected in the context of Lagrange multipliers. The well-known Babuška-Brezzi condition[8,9] must be fulfilled to obtain useful solutions for all involved fields. This indicates that all involved element orders must be chosen carefully to meet these requirements.

2.3.2 Stationary Navier-Stokes flow

The discrete weak form of the stationary Navier-Stokes problem reads: Given density $\varrho \in \mathbb{R}^+$, viscosity $\mu \in \mathbb{R}^+$, body force $\varrho \cdot \boldsymbol{g}^h(\boldsymbol{x})$ in Γ^h, and traction $\hat{\boldsymbol{t}}^h(\boldsymbol{x})$ on $\partial\Gamma^h_{\mathrm{N}}$, find the velocity field $\boldsymbol{u}^h(\boldsymbol{x}) \in \mathcal{S}^h_{\boldsymbol{u}}$, pressure field $p^h(\boldsymbol{x}) \in \mathcal{S}^h_p$, and Lagrange multiplier field $\lambda^h(\boldsymbol{x}) \in \mathcal{S}^h_\lambda$ such that for all test functions $\left(\boldsymbol{w}^h_{\boldsymbol{u}}, w^h_p, w^h_\lambda\right) \in \mathcal{V}^h_{\boldsymbol{u}} \times \mathcal{V}^h_p \times \mathcal{V}^h_\lambda$, there holds in Γ^h

$$
\begin{aligned}
&\varrho \cdot \int_\Gamma \boldsymbol{w}^h_{\boldsymbol{u}} \cdot \left(\left(\boldsymbol{u}^h \cdot \nabla^{\mathrm{cov}}_\Gamma\right)\boldsymbol{u}^h - \boldsymbol{g}^h\right) \mathrm{d}A + \int_\Gamma \nabla^{\mathrm{dir}}_\Gamma \boldsymbol{w}^h_{\boldsymbol{u}} : \boldsymbol{\sigma}\left(\boldsymbol{u}^h, p^h\right) \mathrm{d}A + \int_\Gamma \lambda^h \cdot \left(\boldsymbol{w}^h_{\boldsymbol{u}} \cdot \boldsymbol{n}^h_\Gamma\right) \mathrm{d}A \\
&- \int_{\partial\Gamma_{\mathrm{N}}} \boldsymbol{w}^h_{\boldsymbol{u}} \cdot \hat{\boldsymbol{t}}^h \, \mathrm{d}s + \int_\Gamma w^h_p \cdot \mathrm{div}_\Gamma \, \boldsymbol{u}^h \, \mathrm{d}A + \int_\Gamma w^h_\lambda \cdot \left(\boldsymbol{u}^h \cdot \boldsymbol{n}^h_\Gamma\right) \mathrm{d}A \\
&+ \sum_{\mathrm{e}=1}^{n_{\mathrm{el}}} \int_{\Gamma_{\mathrm{e}}} \tau_{\mathrm{SUPG}} \left(\left(\boldsymbol{u}^h \cdot \nabla^{\mathrm{cov}}_\Gamma\right)\boldsymbol{w}^h_{\boldsymbol{u}}\right) \cdot \left[\varrho \cdot \left(\left(\boldsymbol{u}^h \cdot \nabla^{\mathrm{cov}}_\Gamma\right)\boldsymbol{u}^h - \boldsymbol{g}^h\right) - \mathrm{div}_\Gamma \, \boldsymbol{\sigma}\left(\boldsymbol{u}^h, p^h\right)\right] = 0.
\end{aligned}
$$

The equations related to the different field equations were added up for brevity. The last row adds a stabilization term which is needed to obtain stable solutions for flows at high Reynolds numbers[16,17]. In particular, the streamline upwind Petrov-Galerkin (SUPG) method is used for the stabilization. Different definitions of the stabilization parameter τ_{SUPG} are found[11,18] and $\tau_{\mathrm{SUPG}} = 0$ is used when no stabilization is needed. In the stabilization term, second-order derivatives appear in the element interiors.

2.3.3 Instationary Navier-Stokes flow

The discrete weak form of the instationary Navier-Stokes problem is: Given density $\varrho \in \mathbb{R}^+$, viscosity $\mu \in \mathbb{R}^+$, body force $\varrho \cdot \boldsymbol{g}^h(\boldsymbol{x}, t)$ in $\Gamma^h \times \tau$, traction $\hat{\boldsymbol{t}}^h(\boldsymbol{x}, t)$ on $\partial\Gamma^h_{\mathrm{N}} \times \tau$, and initial condition $u^h_0(\boldsymbol{x})$ on Γ^h at $t = 0$, find the velocity field $\boldsymbol{u}^h(\boldsymbol{x}, t) \in L_2\left(\tau; \mathcal{S}^h_{\boldsymbol{u}}\right)$, pressure field $p^h(\boldsymbol{x}, t) \in L_2\left(\tau; \mathcal{S}^h_p\right)$, and Lagrange multiplier field $\lambda^h(\boldsymbol{x}, t) \in L_2\left(\tau; \mathcal{S}^h_\lambda\right)$ such that for all test functions $\left(\boldsymbol{w}^h_{\boldsymbol{u}}, w^h_p, w^h_\lambda\right) \in \mathcal{V}^h_{\boldsymbol{u}} \times \mathcal{V}^h_p \times \mathcal{V}^h_\lambda$, there holds in $\Gamma^h \times \tau$

$$
\begin{aligned}
&\varrho \cdot \int_\Gamma \boldsymbol{w}^h_{\boldsymbol{u}} \cdot \left(\partial_t \boldsymbol{u}^h + \left(\boldsymbol{u}^h \cdot \nabla^{\mathrm{cov}}_\Gamma\right)\boldsymbol{u}^h - \boldsymbol{g}^h\right) \mathrm{d}A + \int_\Gamma \nabla^{\mathrm{dir}}_\Gamma \boldsymbol{w}^h_{\boldsymbol{u}} : \boldsymbol{\sigma}\left(\boldsymbol{u}^h, p^h\right) \mathrm{d}A + \int_\Gamma \lambda^h \cdot \left(\boldsymbol{w}^h_{\boldsymbol{u}} \cdot \boldsymbol{n}^h_\Gamma\right) \mathrm{d}A \\
&- \int_{\partial\Gamma_{\mathrm{N}}} \boldsymbol{w}^h_{\boldsymbol{u}} \cdot \hat{\boldsymbol{t}}^h \, \mathrm{d}s + \int_\Gamma w^h_p \cdot \mathrm{div}_\Gamma \, \boldsymbol{u}^h \, \mathrm{d}A + \int_\Gamma w^h_\lambda \cdot \left(\boldsymbol{u}^h \cdot \boldsymbol{n}^h_\Gamma\right) \mathrm{d}A \\
&+ \sum_{\mathrm{e}=1}^{n_{\mathrm{el}}} \int_{\Gamma_{\mathrm{e}}} \tau_{\mathrm{SUPG}} \left(\left(\boldsymbol{u}^h \cdot \nabla^{\mathrm{cov}}_\Gamma\right)\boldsymbol{w}^h_{\boldsymbol{u}}\right) \cdot \left[\varrho \cdot \left(\partial_t \boldsymbol{u}^h + \left(\boldsymbol{u}^h \cdot \nabla^{\mathrm{cov}}_\Gamma\right)\boldsymbol{u}^h - \boldsymbol{g}^h\right) - \mathrm{div}_\Gamma \, \boldsymbol{\sigma}\left(\boldsymbol{u}^h, p^h\right)\right] = 0.
\end{aligned}
$$

This yields a system of non-linear semi-discrete equations with initial condition $\underline{\boldsymbol{u}}(0)$. This system may be advanced in time by using finite difference schemes and the Crank-Nicolson method is employed herein.

3 NUMERICAL RESULTS

A number of test cases have already been proposed in[12]. Herein, two more test cases are suggested and even higher element orders are used for the approximations.

Because analytic solutions are hardly available in the context of flows on curved surfaces, we find it useful to study the error in the strong form of the governing equations as given in Section 2.2. Of course, due to the C_0-continuity of the FE shape functions, those equations involving second-order derivatives may only be integrated over element interiors (just as the stabilization terms from above). For the example of stationary Stokes flow, the corresponding residual errors are defined as

$$\varepsilon_{\mathrm{mom}} = \sqrt{\sum_{\mathrm{e}=1}^{n_{\mathrm{el}}} \int_{\Gamma_{\mathrm{e}}} \left(\mathbf{P} \cdot \mathrm{div}_\Gamma \, \boldsymbol{\sigma} \left(\boldsymbol{u}^h, p^h \right) + \boldsymbol{f}^h \right)^2 \mathrm{d}A} \tag{16}$$

and

$$\varepsilon_{\mathrm{cont}} = \sqrt{\int_\Gamma \left(\mathrm{div}_\Gamma \, \boldsymbol{u}^h \right)^2 \mathrm{d}A}, \qquad \varepsilon_{\mathrm{tang}} = \sqrt{\int_\Gamma \left(\boldsymbol{u}^h \cdot \boldsymbol{n}_\Gamma^h \right)^2 \mathrm{d}A}. \tag{17}$$

This can be easily extended to the case of Navier-Stokes flows where the advection term is added to the integrand in (16).

3.1 Stationary flow on a deformed ring

A flow is considered on a deformed ring as shown in Fig. 2(a). The domain is generated using an annulus with inner radius $R_{\mathrm{in}} = 0.5$ and outer radius $R_{\mathrm{out}} = 1.0$ as a starting point, that is, $\Omega_{\boldsymbol{r}} = \{ \boldsymbol{r} \in \mathbb{R}^2 : R_{\mathrm{in}} \leq \| \boldsymbol{r} \| \leq R_{\mathrm{out}} \} \subset \mathbb{R}^2$. This annulus is associated with a third dimension using the coordinate

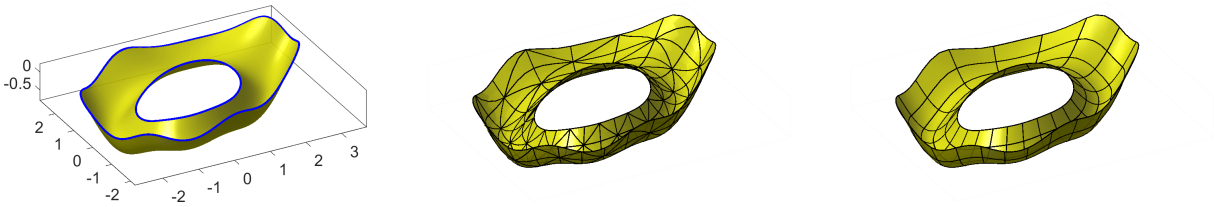
$$t\left(\boldsymbol{r}\right) = 1 - \frac{\exp\left(-1/2 \left(\frac{\| \boldsymbol{r} \| - \mu}{\sigma} \right)^2 \right)}{\sqrt{2\pi\sigma}}, \quad \text{with} \quad \mu = 3/4 \text{ and } \sigma = 1/4.$$

This yields a manifold $\Gamma_{\boldsymbol{r}}$ in the three-dimensional coordinate system (r, s, t) which is further deformed with a map $\boldsymbol{x}\left(\boldsymbol{r}\right)$ as

$$\begin{aligned} x\left(\boldsymbol{r}\right) &= \tilde{r} + \tilde{r}^2 + 1/10 \cdot \sin\left(\tilde{r}\right) - 3, \\ y\left(\boldsymbol{r}\right) &= \tilde{s} + 1/2 \cdot \tilde{s}^2 + 1/10 \cdot \cos\left(\tilde{s}\right) - 2, \\ z\left(\boldsymbol{r}\right) &= t + 1/5 \cdot \sin\left(x\left(\boldsymbol{r}\right) \cdot y\left(\boldsymbol{r}\right) \right), \end{aligned}$$

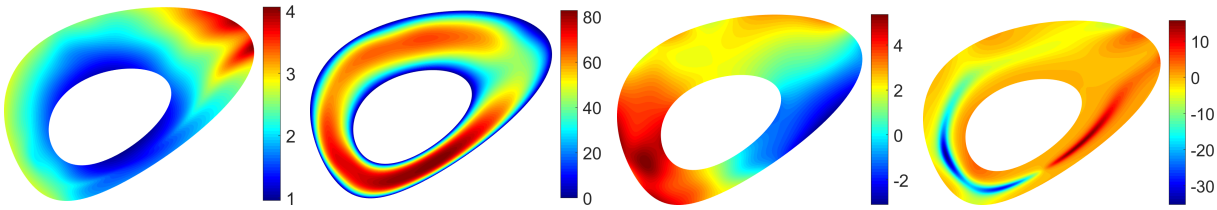
with $\tilde{r} = 1.2 + r$ and $\tilde{s} = 1.2 + s$. A rigid body rotation by 30° around the z-axis yields the manifold of interest Γ.

It is simple to generate meshes with the desired number of elements in radial and circumferential direction. Examples for meshes composed of quadrilateral and triangular elements are seen in Figs. 2(b) and (c).



(a) domain (b) tri-mesh (c) quad-mesh

Figure 2: Ring test case: (a) domain, and meshes composed by (b) triangular and (c) quadrilateral elements.



(a) $\|\boldsymbol{f}_t(\boldsymbol{x})\|$ (b) $\|\boldsymbol{u}(\boldsymbol{x})\|$ (c) $p(\boldsymbol{x})$ (d) $\lambda(\boldsymbol{x})$

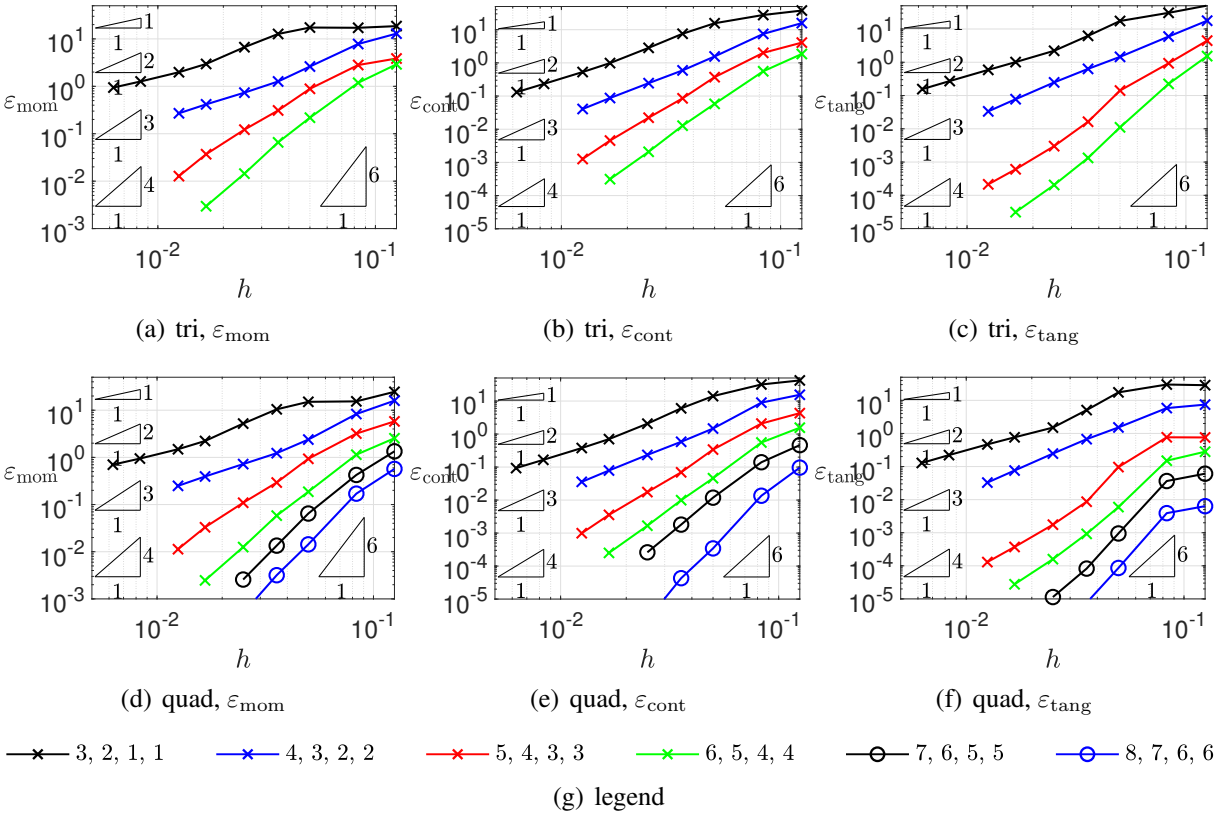
Figure 3: Ring test case from top view: (a) acceleration magnitude, (b) velocity magnitude, (c) pressure, and (d) Lagrange multiplier field.

The density and viscosity are set to $\varrho = 1$ and $\mu = 0.01$, respectively. No-slip boundary conditions are applied at *all* boundaries. This is because inflow and outflow boundary conditions may render the generation of higher order accurate results difficult. The flow is driven by an acceleration field

$$\boldsymbol{g}(\boldsymbol{x}) = \begin{bmatrix} g_x \\ g_y \\ g_z \end{bmatrix} = \begin{bmatrix} -y \\ x \\ 0 \end{bmatrix} \quad \Rightarrow \quad \boldsymbol{f}_t(\boldsymbol{x}) = \varrho \cdot \mathbf{P}(\boldsymbol{x}) \cdot \boldsymbol{g}(\boldsymbol{x}) .$$

A graphical representation of the driving forces $\boldsymbol{f}_t$, and the resulting solutions for the velocity magnitude, the pressure and the Lagrange multiplier are seen in Fig. 3 (when looking in z-direction on the manifold).

For the convergence studies, finite element approximations are carried out on various meshes composed by triangular or quadrilateral Lagrange elements of different orders. Meshes with $n_R = \{4, 6, 10, 14, 20, 30, 40, 60, 80, 100\}$ elements in radial direction and $n_\theta = 4 \cdot n_R$ elements in circumferential direction are used. The individual element orders used for the convergence studies are indicated by a 4-tuple $\{k_{\text{geom}}, k_{\boldsymbol{u}}, k_p, k_\lambda\}$. To be precise, this tuple summarizes the employed orders for the geometry, k_{geom}, the velocities, $k_{\boldsymbol{u}}$, the pressure, k_p, and the Lagrange multiplier for enforcing the tangential velocity constraint, k_λ. For each tuple, meshes with different resolutions (given by n_R and n_θ) are considered and errors calculated, each time resulting



(a) tri, $\varepsilon_{\mathrm{mom}}$ (b) tri, $\varepsilon_{\mathrm{cont}}$ (c) tri, $\varepsilon_{\mathrm{tang}}$

(d) quad, $\varepsilon_{\mathrm{mom}}$ (e) quad, $\varepsilon_{\mathrm{cont}}$ (f) quad, $\varepsilon_{\mathrm{tang}}$

(g) legend

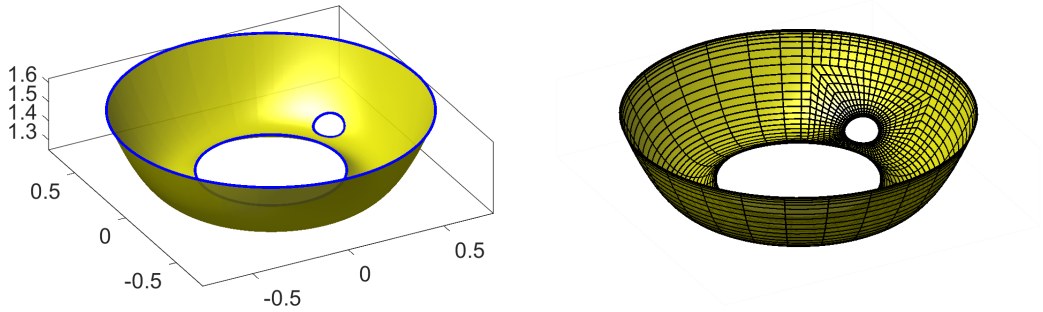
Figure 4: Convergence results in $\varepsilon_{\mathrm{mom}}$, $\varepsilon_{\mathrm{cont}}$, and $\varepsilon_{\mathrm{tang}}$ for the ring test case, (a) to (c) for triangular elements, (d) to (f) for quadrilateral elements. The legend in (g) decodes the orders $\{k_{\mathrm{geom}}, k_{\boldsymbol{u}}, k_p, k_\lambda\}$ of the meshes.

in one curve in the convergence plots as indicated in the legends. The preferred setting, as already suggested in [12,13], is to choose $k_{\mathrm{geom}} = k_{\boldsymbol{u}} + 1$ and $k_p = k_\lambda = k_{\boldsymbol{u}} - 1$ for some given $k_{\boldsymbol{u}}$. With respect to the orders of the velocities compared to the pressure, this is a Taylor-Hood element [19].

Convergence results are seen in Fig. 4. Triangular elements are considered with $2 \leq k_{\boldsymbol{u}} \leq 5$ and are seen in Figs. 4(a) to (c). Quadrilateral elements are investigated with $2 \leq k_{\boldsymbol{u}} \leq 7$ and results shown in Figs. 4(d) to (f). It is clearly seen that higher-order convergence rates in $\varepsilon_{\mathrm{mom}}$, $\varepsilon_{\mathrm{cont}}$, and $\varepsilon_{\mathrm{tang}}$ are achieved. Because second order derivatives are involved in the computation of $\varepsilon_{\mathrm{mom}}$, the convergence rates are (up to) one order less than for $\varepsilon_{\mathrm{cont}}$ and $\varepsilon_{\mathrm{tang}}$.

3.2 Instationary cylinder ring flow

The next example is an instationary Navier-Stokes flow on a ring-like surface with a cylindrical hole, see Fig. 5(a). An example mesh is seen in Fig. 5(b) and elements are refined to resolve the boundary layers. The density and viscosity are prescribed as $\varrho = 1.0$ and $\mu = 0.001$. The



(a) domain (b) mesh

Figure 5: Cylinder test case: (a) domain and (b) mesh.

starting point to generate the curved manifold is the flat two-dimensional cylinder flow according to[20]. The geometry is first described in 2D based on the coordinates (a, b), labelled $\Omega_{\boldsymbol{a}}$, and later on mapped to obtain the curved surface Γ in 3D. In 2D, the cylinder with a diameter of 0.1 is placed slightly unsymmetrically in y-direction of the channel in $[0, 2.20] \times [0, 0.41]$. The curved manifold is then obtained using the following map,

$$\begin{aligned} x(\boldsymbol{a}) &= \cos(\alpha) \cdot (b + 7/20), \\ y(\boldsymbol{a}) &= \sin(\alpha) \cdot (b + 7/20), \\ z(\boldsymbol{a}) &= 2 + 1/2 \cdot d(x, y) - \sin(3 \cdot d(x, y)), \end{aligned}$$

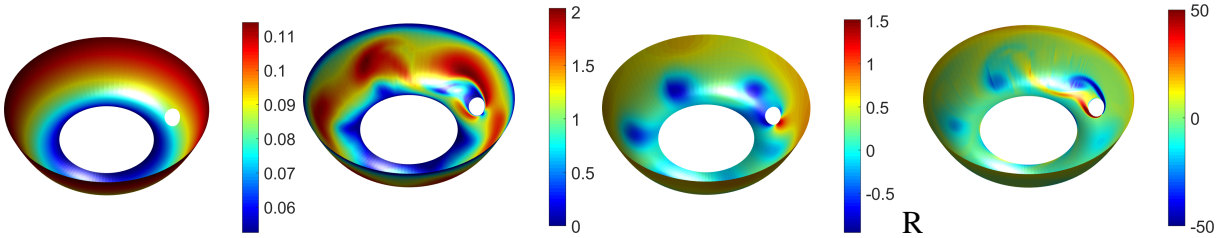
with $\alpha = 10/11 \cdot \pi \cdot a$ and $d(x, y) = \sqrt{x^2 + y^2}$.

The flow is driven by a rotational acceleration field,

$$\boldsymbol{g}(\boldsymbol{x}) = \begin{bmatrix} g_x \\ g_y \\ g_z \end{bmatrix} = \begin{bmatrix} -y \\ x \\ 0 \end{bmatrix} \cdot g^\star,$$

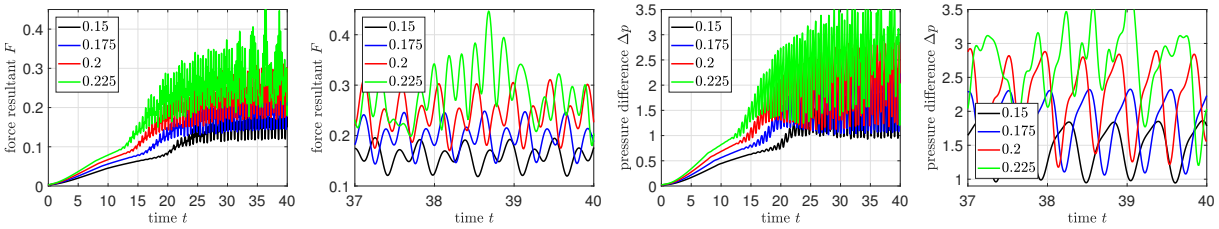
scaled by the parameter $g^\star = \{0.15, 0.175., 0.2, 0.225\}$. The situation is observed in the time interval $t \in [0, 40]$. For $g^\star = 0.15$ and at time $t = 40$, the resulting velocity magnitude, pressure, and vorticity are shown in Fig. 6. It is clearly seen that periodic flow patterns known as the Kármán vortex street are observed behind the cylinder.

Element orders of $k_{\text{geom}} = 4$, $k_{\boldsymbol{u}} = 3$, $k_p = 2$ and $k_\lambda = 2$ are chosen in the numerical studies. 4000 time steps are employed in the Crank Nicolson method. Higher orders or more time steps achieved virtually indistinguishable results for the quantities shown below. To make the results more quantitative, the stresses at the cylinder wall are summed up to obtain a force resultant $F(t) = \|\boldsymbol{F}(t)\|$ in 3D. This is the equivalent of the lift and drag coefficients for the flat 2D case. Furthermore, the pressure difference between the front and back position of the cylinder (in Ω_{2D}, mapped to three dimensions) is computed, i.e., $\Delta p(t) = p_{\text{front}}(t) - p_{\text{back}}(t)$. Results are shown in Fig. 7 for the different values of $g^\star$ scaling the acceleration field. Choosing



(a) $\|\boldsymbol{a}_{\mathrm{T}}(\boldsymbol{x})\|$ (b) $\|\boldsymbol{u}(\boldsymbol{x})\|$ (c) $p(\boldsymbol{x})$ (d) $\omega(\boldsymbol{x})$

Figure 6: Cylinder test case for $g^\star = 0.15$ at time $t = 40$: (a) acceleration magnitude, (b) velocity magnitude, (c) pressure, and (d) vorticity.



(a) $F(t), t \in (0, 40)$ (b) $F(t), t \in (37, 40)$ (c) $\Delta p(t), t \in (0, 40)$ (d) $\Delta p(t), t \in (37, 40)$

Figure 7: Force resultant $F(t)$ and pressure difference $\Delta p(t)$ obtained for the cylinder flow test case.

higher values for $g^\star$ may no longer lead to periodic but rather chaotic results. It is seen that the acceleration field has to act for about 15 seconds until the flow field changes from steady to periodic flow patterns. For $t \geq 35$, the flow patterns are fully established for $g^\star \leq 2$.

4 CONCLUSIONS

A mixed, stabilized, higher-order accurate surface finite element method is considered for stationary and instationary Stokes and Navier-Stokes flows on curved surfaces in three dimensions. It is found that when the orders of the involved fields are suitably chosen, higher-order convergence rates are achieved. A particularly useful combination for a given $k_{\boldsymbol{u}}$ is $k_{\mathrm{geom}} = k_{\boldsymbol{u}} + 1$ and $k_p = k_\lambda = k_{\boldsymbol{u}} - 1$. Future works shall investigate different stabilization methods and approaches to enforce the tangential velocity constraint. It is found that flows on manifolds have a strong potential for fundamental research in mathematics, physics, and engineering.

Poroelastic Assessment of Interstitial Fluid Flow Around Osteocytes in Osteoporotic Conditions

Susannah Fritton*, Vittorio Gatti**, Evan Azoulay***, Michelle Gelbs****, Michael Gerber*****

*The City College of New York, **The City College of New York, ***The City College of New York, ****The City College of New York, *****The City College of New York

ABSTRACT

The objective of this work was to assess whether interstitial fluid flow, which is critical for bone's mechanosensory system, is compromised in osteoporotic bone. Using poroelastic finite element modeling, we investigated whether changes in bone's microporosity, including the vascular and lacunar-canalicular porosities, can affect interstitial fluid flow. Two pre-clinical models were assessed: a rat ovariectomy model of postmenopausal osteoporosis, and a rat muscle-paralysis model of disuse osteoporosis. Animal-specific finite element models were created from high-resolution micro-CT scans of rat tibiae for estrogen-deficient (n=12) and disuse (n=16) experiments. The results demonstrate that increased vascular porosity due to either estrogen deficiency or disuse decreases interstitial fluid flow around osteocytes embedded in the bone cortex. By comparing the results of the two modeling studies we conclude that changes in the lacunar-canalicular fluid velocity are proportional to the increase in vascular porosity (or decrease in vascular pore separation). While vascular porosity negatively influenced bone fluid flow, it was more difficult to elucidate potential effects of changes in the lacunar-canalicular porosity for both the estrogen deficiency and disuse conditions. In the disuse study, we were able to improve the animal-specific modeling approach by representing the osteocytic lacunar network within the micro-CT derived finite element models. The rats subjected to muscle paralysis demonstrated a reduced lacunar density, but the results of the numerical analysis revealed no correlation of the reduced lacunar density with the average fluid velocity near the lacunae. An important improvement of the finite element modeling approach with the disuse project was the possibility of predicting fluid flow around a large number of osteocyte lacunae. Advancement in the imaging and computational methods allowed the quantification of the fluid flow around 500-1000 osteocyte lacunae, contained in relatively large volumes of bone cortex. This method can provide a significant advantage in describing bone's mechanosensory system at a multiscale level: from the single osteocyte response to the macroscopic whole-bone changes, including a mesoscale level, where a group of osteocytes (100-1000) can locally respond in a concerted way. Our modeling approach led to the important observation that fluid velocity around osteocytes depends largely on their specific position in the cortex. This could explain the variability of the morphology and function of the osteocytic network. In future studies, we can use this modeling approach to compare fluid flow around osteocytes with their specific biological activity, helping to bridge the gap between different scales of functional adaptation mechanisms.

Validating the Tsunami Propagation Model Geoclaw, Based on the 1995, Mw7.2 Nuweiba Earthquake

Eran Frucht*, Amos Salamon**, Rachamim Shem Tov***, Hanan Ginat****, Erez Gal*****

*Department of Structural Eng., Ben-Gurion University, **Geological Survey of Israel, ***The Dead Sea-Arava Science Center (DSASC), ****The Dead Sea-Arava Science Center (DSASC), *****Department of Structural Eng., Ben-Gurion University

ABSTRACT

The tsunami reported after the strong Mw7.2 1995 Nuweiba earthquake, together with prehistoric tsunamites found along the head of the Gulf of Elat-Aqaba (GOA) and the adjacent Red Sea, emphasize the natural hazard there. The Gulf is located along the southern part of the Dead Sea Transform, which is an active system that generates frequent strong and destructive earthquakes. The presence of a water body inside the Gulf produces potential for a tsunami by submarine earthquakes and landslides. Here we investigate the 1995 Nuweiba tsunami and validate our numerical model, as part of the preliminary evaluation of tsunami hazard along the Head of the Gulf. First, we constructed the bathymetry and topography grid of the Gulf. Next, we adopted the GeoClaw tsunami modeling program, which can solve 2D depth-averaged shallow water equations, simulate wave propagation and compute tsunami wave heights and inundation. We then simulated the 1995 Nuweiba tsunami and produced time series of the expected wave height in several artificial gauges along the northern part of the Gulf. Based on various models of the source parameters of the 1995 Nuweiba earthquake, four different scenarios were simulated. The results were then compared with field evidence, eyewitness reports and the recorded mareogram, as well as with the numerical model proposed by Abril et al. (2017). Overall, the results show relatively small waves, in the order of and in accordance with the field observations, the recorded mareogram and the numerical model of Abril et al. The findings provide profound validation of the GeoClaw model. The methodology and outcomes of this work lay down the foundation for a thorough and systematic evaluation of the tsunami hazard in this area.

Conceptual Design of a Soft Material Linear Switched Reluctance Motor for Soft Robotic Applications

Arian Fröhlich*, Christoph Thon**, Franz Dietrich***, Carsten Schilde****

*Institute of Machine Tools and Production Technology, Technische Universität Braunschweig, **Institute for Particle Technology, Technische Universität Braunschweig, ***Institute of Machine Tools and Production Technology, Technische Universität Braunschweig, ****Institute for Particle Technology, Technische Universität Braunschweig

ABSTRACT

Common actuation principles in soft material robotics require rigid components in their chain of energy conversion devices, for example fluid pumps or tendon winding motors. In a strict sense, their embodiment in a robot, can hardly be called structurally “soft”. There are other actuation principles that use elastic or pseudo-elastic materials to transform electrical power into motion in “soft” structures directly, for example shape memory alloys and electro-active polymers. Nevertheless, power limits or travel range limits, performance quality, short material life time, electrical hazards or further practical difficulties may inhibit their deployment. This need for soft actuation principles with high power density, large travel ranges, manufacturable design, robustness, and simple systems integration is the motivation for this approach. In order to establish all-soft actuators, this approach strives for direct conversion of electrical power into motion by electro-magnetism. It is the objective to elaborate the fundamentals of electro-magnetic actuators which consist of highly elastic materials so that, ultimately, such devices can be embedded into soft robot structures without disturbing the robot’s structural softness. Among the electro-magnetic motor principles, the switched reluctance motor is identified as the research subject of highest priority, because the realization of effective elastic magnetic flux guidance therein is a preliminary technology for the other, more complex electromagnetic motor principles. In order to yield the actuation force, such an actuator requires a set of coil-driven magnetic circuits, which change their inductances when the mover travels. It is proposed to realize the magnetic circuit, which has to guide the magnetic flux through the coil and the mover, by an elastic material filled with ferro-magnetic particles. Hereby, the main technical target is to maximize the amplitude change of the magnet circuit’s inductance. The key to an effective actuator design addressed by this approach lies hence in a combination of particle embedding technology in complex shapes for effective magnetic flux geometries and model-based systems engineering that considers the cross-domain complexity of such actuators. Both are supported by function- and manufacturing-oriented simulations, such as a coupled DEM simulation for particle-filled flux guidance geometries.

Two Scale Topology Optimization of Shell-infill Structures Using Level Set Method

Junjian Fu*, Liang Gao**, Hao Li***, Mi Xiao****

*State Key Lab of Digital Manufacturing Equipment and Technology, Huazhong University of Science and Technology, China, **State Key Lab of Digital Manufacturing Equipment and Technology, Huazhong University of Science and Technology, China, ***State Key Lab of Digital Manufacturing Equipment and Technology, Huazhong University of Science and Technology, China, ****State Key Lab of Digital Manufacturing Equipment and Technology, Huazhong University of Science and Technology, China

ABSTRACT

This paper proposed a two scale topology optimization method for shell-infill structures based on level set method. Two level set functions are utilized to represent the structural boundaries of macro shell and the micro infill, respectively. In the macroscopic, the design of the shell structure is defined as a compliance minimization problem. The macro shell is captured by the contour area between the zero and the k level set. The value of k is equal to the thickness of the shell. A reinitialization scheme is imposed on the macro level set function to guarantee a uniform thickness of the shell. In the microscopic, the infill is designed by periodic microstructures with the same configuration. Viewing the compliance of macro structure as the objective function, these microstructures are optimized based on level set method. The numerical homogenization method is applied to evaluate the effective elasticity tensor of the microstructure, which bridges the connection between the microstructure and the macro material property. Both 2D and 3D numerical examples are investigated to demonstrate the effectiveness of the proposed method. Results indicate that this method is of great potential in the design of bio-inspired and additive manufacturing oriented structures. High-order Targeted ENO Scheme for Turbulence Simulations

Lin Fu*, Nikolaus A. Adams**

*Center for Turbulence Research, Stanford University, **Chair of Aerodynamics and Fluid mechanics, Technical University of Munich

ABSTRACT

In this paper, we present a high-order targeted ENO scheme, which shows exceptional performance in conventional compressible gas dynamics, extreme simulations (Mach number of 2000), incompressible and compressible turbulence reproduction. For conventional compressible gas dynamics, the TENO scheme is robust, and shows low numerical dissipation in resolving high-wavenumber physical fluctuations while capturing the discontinuities sharply. For the extreme simulations, the proposed scheme is numerically stable and preserves the ENO property. In terms of turbulence simulations, it can faithfully predict the energy transfer for incompressible flows, resolve the vorticity, entropy and acoustic models for compressible flows. A set of benchmark simulations will be computed to validate the performance of proposed scheme.

Variational Approach of Coarse-grained Lipid Dynamics Based on Potential for Amphiphilic Molecules

Szu-Pei Fu*, Rolf Ryham**, Yuan-Nan Young***

*Fordham University, **Fordham University, ***New Jersey Institute of Technology

ABSTRACT

In macroscopic models, the well-known Helfrich Hamiltonian membrane model has been extensively used to capture macroscopic physical properties of a lipid bilayer membrane. Some phenomena such as membrane fusion and micelle formation are, however, challenging to described using a macroscopic framework, and including all the molecular details has its challenges, from a numerical simulation perspective. Therefore, in order to include the salient molecular details in a coarse-grained manner, we study the dynamics of lipid bilayer membrane using Janus-type particle configurations to represent collections of lipids. These coarse-grained lipid molecules interact through an action field that measures water activity due to the presence of nearby hydrophobic surfaces, leading to specific boundary conditions on each Janus particle. We adopt two numerical frameworks to investigate the particle dynamics: (1) the finite element method (FEM); (2) the quadrature by expansion method. We also examine the numerical accuracy and qualitative comparisons for large system simulations, and compare with other potential-theoretic methods.

3D Numerical Simulation on the Interaction between Hydraulic Fractures and Natural Fractures with Spatially-Varied Properties

Wei Fu*, Alexei Savitski**, Branko Damjanac***, Andrew P. Bunger****

*University of Pittsburgh, **Shell, ***Itasca Consulting, ****University of Pittsburgh

ABSTRACT

The estimation of hydraulic fracture (HF) propagation in fractured unconventional reservoirs is important for the reservoir stimulation design. Previous studies typically assume that natural fractures (NFs) have uniform properties and persist through the full height of the reservoir/HF, which lead to 2D views. Recent field and experimental observations, on the other hand, demonstrate that the spatial variation of NF properties can strongly influence the HF propagation patterns. In this study, a lattice model that fully couples fluid flow with rock matrix represented by quasi-randomly distributed nodes (discrete masses) and springs is employed to simulate the 3D interaction between HFs and NFs with non-uniform properties. The numerical simulations capture the strong dependence of HF propagation patterns on the NF heterogeneities, characterized by different cementation strength, cemented proportions and/or height. In a parametric study of NF properties, the simulations are observed to match an experimentally verified 3D analytical criterion well for cases with varying mechanical and/or geometrical NF properties. The simulation results also reveal that 3D interactions between HFs and NFs are not only related to localized interaction behaviors determined by local interface conditions as considered in 2D crossing criteria, but also global interaction behaviors that are influenced by the overall properties of encountered NFs.

Art of Balancing and Conforming in Discrete Elements of Continuum

XiangRong Fu*, Pu Chen**, MingWu Yuan***

*Department of Civil Engineering?China Agricultural University, **Department of Mechanics and Engineering Science, PeKing University, ***Department of Mechanics and Engineering Science, PeKing University

ABSTRACT

A review on the basic theories of the finite element method or the associated computational method are presented in the paper. Some classic theories of discrete elements are studied, and some novel models of discrete elements are presented. In the view of balancing, the analytical trial functions which satisfy equilibrium equations are used to construct the stress field in the novel discrete elements. In the view of conforming, the isoparametric elements, the non-conforming elements and the super conforming elements are compared with each other in two-dimension problems . Following different theories of balancing or conforming, every kind of discrete elements forms the basic theory of the finite element method or the associated computational method. The benchmark tests show that the discrete elements combining two characters who can satisfy the equilibrium equation in the element and take into the conforming boundary condition around the element can give better perform.

ABSTRACT

Designing novel structural materials with complex shape and geometry is enabled with the advancement of additive manufacturing processes, to meet specific performance requirements that are not imaginable with traditional subtractive manufacturing techniques. The microstructure evolution during the repeated heating/cooling process determines the various properties of manufactured products. Modeling and simulation can advance our fundamental understanding of the underlying physical processes and capability to quantify the influence of process variables on resulting component properties. Therefore, it plays an increasingly crucial role for the design and optimization of components and materials. In this study, the prediction of microstructural evolution during the additive manufacturing process is realized through the phase field modeling at the meso and micro length scale. Coupled with heat conduction equation where the latent heat of fusion is considered, the temporal and spatial evolution of the melting pool is simulated at the mesoscale with the Kim-Kim-Suzuki (KKS) model. The temperature history provides input for the microscale model, where the microstructural evolution such as dendritic growth can be predicted during the laser-materials interaction via the multiphase KKS model.

Parallelization of Microscopic Traffic Simulator and Its Load Balancing

Hideki Fujii*, Yuta Ushimaru**, Tomonori Yamada***, Shinobu Yoshimura****

*The University of Tokyo, **The University of Tokyo, ***The University of Tokyo, ****The University of Tokyo

ABSTRACT

In order to evaluate transportation policies quantitatively, virtual social experiments using traffic simulators are adequate. It is because experiments in the real road environment are impracticable for predicting traffic phenomena as complex systems, and even small changes in conditions can affect to wide area significantly. In particular, simulators with features of both precision and scalability are preferable for applications to real-world traffic issues. In this research, we tried to parallelize a multi-agent-based traffic simulator [1, 2] using a graph partitioning approach. Cars are modeled as autonomous agents in the simulator. A car agent acquires information from its circumference (other cars, traffic signals, etc.), makes a decision autonomously, and acts accordingly. The precision is accomplished by employing a multi-agent system and realistic car behavior models, and the scalability is advanced by parallelization in this approach. Since the perceptions of the determinants for decision making of a car agent being driven are limited locally, it is reasonable to decompose road network to subnetworks. We utilized METIS [3] as a graph-partitioning tool to minimize edge cuts. The computational cost of a subnetwork in the simulation depends on the number of agents on the subnetwork and the numbers are not constant among each subnetwork. That causes load imbalance. We tested to give weights to edges to improve the imbalance. We show the result of graph partitioning approach and its parallelization performance in the presentation. Our approach contributes to import the methods that have been discussed in the field of computational mechanics to the new field of social simulation. [1] S. ABSTRACT

Concrete-filled-tubes (CFTs) are used as columns of architectural and civil engineering structures. CFTs usually have large deformation capacity due to lateral constraints from steel tubes providing ductility. In some of existing studies on numerical analysis of CFTs, constraint effect such as lateral pressure between steel and concrete is obtained from experiments and considered in analysis as additional forces, etc. However, to the best of authors' knowledge, no numerical analysis method, which can simulate behaviors of CFTs under cycling loading, has been proposed. The authors have been developing a detailed finite element analysis system called E-Simulator[1,2]. In this research project, we simulate structural behavior only by combining detailed solid finite element model and material constitutive laws, which can represent damages and fractures of materials. By using E-Simulator, we can consider interaction between filled concrete and steel tube without any additional constraint effects. In this study, a detailed finite element analysis of a CFT column is conducted to simulate collapse behavior under lateral cyclic loading. In our analysis, concrete is modeled as an elastoplastic material with extended Drucker-Prager yield condition that has a smooth yield surface in tension. Softening behavior in compression is formulated based on simple damage criteria. A piecewise linear isotropic-kinematic hardening model[3] is applied to steel. We simulate a cyclic shear-bending loading experiment of a CFT column. The height is 1440 mm and the section is a 240?240 mm square tube. A pseudo-static cyclic lateral displacement with increasing amplitude is given at the top of the column under vertical load. According to the comparison of load-deformation relations obtained from the experimental and numerical results, analysis result corresponds fairly well to the experimental one. The progress of damage in the filled concrete and the steel-concrete interaction is visually illustrated in the numerical result, while it is difficult to quantify in experiments. References [1] M. Simulation-based Assessment of Railway Dynamic Gauge for the Conception of New Trains

Christine Funfschilling*, Guillaume Perrin**

*SNCF, **CEA/DAM/DIF

ABSTRACT

In order to ensure the safety of a railway circulation, it is necessary to estimate the railway gauge to verify that the rolling stock will not run too close to the infrastructure or to another train running on an adjacent track. Currently, in France, the railway gauge is assessed thanks to an empirical deterministic approach stemming from extended experimental work. The vehicle-track system is however complex and contains several sources of uncertainties: the track irregularities, the wheel-rail contact shape and the friction coefficient, the mechanical suspension properties, the wind gusts and so on. The use of multi body simulation coupled with a probabilistic approach could thus present several advantages ; for a given train and a given railway network, we will focus here on the assessment of the risk that the dynamic gauge may not be in accordance with the certification rules. In this work, we thus propose a method to evaluate the envelope of the position of the train. To take into account the uncertainties that are inherent to the system, a probabilistic approach is developed, leading to a random envelope of the train. A three step method is adopted to evaluate the probability that the certification criteria may not be fulfilled. The first step consists in sampling a set of realistic track irregularities with a stochastic generator. This latter is based on a high dimensional non-Gaussian random field that has been identified on a large set of measurements. A Monte Carlo algorithm is used for the sampling. Railway dynamic simulations are then achieved in parallel with the commercial software Vampire. Finally the obtained displacements are processed to estimate the desired random envelope. Since very low probabilities are of interest, dedicated methods are needed for the evaluation of the final probability. A Moving Particle algorithm coupled with a Markov Chain Monte Carlo procedure is considered here, which is a particularly efficient subset method for the estimation of the probability of rare events. This is particularly important here, as the computational cost of each evaluation of the railway software is relatively high.

Materials Genomics and the Future of Structural Alloy Design and Application

David Furrer*

*Pratt & Whitney

ABSTRACT

Computational materials engineering has evolved through parallel advancement of materials characterization, physics-based understanding of materials behavior, computational modeling methods, informatics and computational methods. These linked advancements have been significant steps toward to the application of Integrated Computational Materials Science and Engineering (ICMSE). Formalized materials genomics activities are increasing the rate of new material development for future, unique requirements. Materials genomics and computational materials methods have been advanced to a point where they are being substantially accepted by industry and the larger interdisciplinary engineering community. This talk will review major enabling materials genomics technologies relative to industrial applications for the design and development of next generation materials.

ABSTRACT

Frozen porous media consist of solid skeleton, pore fluid, and ice matrix. This mechanical model has been proposed by Leclaire et al [1] and well known as an extended model based on the fluid-saturated porous media proposed by Biot [2]. Recently, the frozen porous media attract a great deal of attention from researchers in the field of the geophysical exploration because this model is adequate to describe the dynamic behavior of seabed layer involving methane hydrate. Body waves in the frozen porous media propagate with dispersion and dissipation in the same manner as waves in the fluid-saturated porous media. In addition, antiplane shear wave has two propagation modes, i.e. S1- and S2-modes [3]. Therefore, it is important to consider the interaction among three phases for the evaluation of wave scattering properties of the frozen porous media. However, there are few reports with regard to the development of numerical computation methods for wave scattering by an inclusion which involves highly concentrated hydrate. This study presents a numerical simulation to understand the characteristics of wave scattering by a hydrate inclusion in the seabed layer. The problem is formulated by a boundary element method (BEM) which can deal with the antiplane shear waves in the frozen porous media. Several numerical examples are shown to provide the validity of our proposed method and scattering properties resulting from the numerical simulation. [1] Ph. Leclaire, F. Cohen-Tenoudji and J. ABSTRACT

Thermoelectric devices are unique in that they can convert thermal energy to electric energy and vice versa. When a temperature gradient between two different points exists on a thermoelectric device, a voltage is generated. Conversely, when a voltage is applied between two different points on a thermoelectric device, a thermal gradient is produced. The former effect is called the Seebeck effect and is exploited in power generation systems. The latter is called the Peltier effect and is employed in cooling devices and temperature-control systems. The advantages of thermoelectric devices are compactness, lack of moving parts, maintenance-free operation, longevity, and ability to be precisely controlled, properties that have led to their broad use in various fields. Despite their utility, however, thermoelectric devices are typically deployed only in niche applications due to their comparatively low the efficiency of energy conversion, only 5% in conventional commercial modules. In recent years, dramatic improvements in nano-fabrication techniques have enabled the design of materials and devices that take nanoscale phenomena into account. Manipulating such nanostructures can enable only decrease the thermal conductivity by utilizing the phonon reflections in material interfaces, and provide novel material properties for thermoelectric materials [1]. However, little research has focused on design methods for nanoscale thermoelectric devices, since this requires consideration of properties that are discontinuous on material interfaces. Here, we propose a structural optimization method for nanoscale heat conduction problems based on a level-set method. First, we define the optimization problem using the phonon Boltzmann transport equation that can model temperature discontinuities on material interfaces when dealing with heat conduction at the nanoscale. The shape sensitivity is then computed with an adjoint method that considers discontinuous properties on material interfaces [2]. A Hamilton-Jacobi equation is applied when updating the level-set function that represents the structure [3]. Finally, numerical examples confirm the validity of our proposed structural optimization method. [1] J. Yu, S. Mitrovic, D. Tham, J. Varghese and J. ABSTRACT

We present results of our recent work [1], where we derive and analyse discontinuous Petrov–Galerkin methods with optimal test functions for Signorini-type problems as a prototype of a variational inequality of the first kind. We present different symmetric and nonsymmetric formulations, where optimal test functions are used only for the partial differential equation part of the problem, not the boundary conditions. For the symmetric case and lowest-order approximations, we provide a simple a posteriori error estimate. Moreover, we apply our technique to the singularly perturbed case of reaction-dominated diffusion. Numerical results show the performance of our method and, in particular, its robustness in the singularly perturbed case. References: [1] T. Führer, N. Heuer, E.P. ABSTRACT

In dynamic transient analysis, recent comprehensive studies have shown that using mass penalty together with standard stiffness penalty, the so-called bipenalty technique, preserves the critical time step in conditionally stable time integration schemes. In Reference [1] the stability and reflection-transmission analysis of the bipenalty method has been studied for one-dimensional contact-impact problems. The main attention has been paid on an upper bound estimation of the stable Courant number for the bipenalty method with respect to stiffness penalty and mass penalty parameters. This analysis has been carried out for several basic one-dimensional contact problems. In this work, the bipenalty technique is applied for the solution of two-dimensional contact-impact problems. The bipenalty method is implemented to an explicit contact algorithm based on the symmetry preserving penalty formulation [2]. The attention is focused on the stability properties of this algorithm using the derived upper bound of the stable Courant number. Next, the estimation of the stiffness and mass penalty parameters ensuring non-oscillating behavior is investigated. Several numerical examples are presented including the longitudinal impact of two thick plates/cylindrical rods, for which an analytical solutions are available. In all the cases the superiority of the bipenalty method over the standard stiffness penalty method is demonstrated. A Novel Framework for Joint Task and Manufacturing Optimization of Multi-Material Soft Robots

Felix Gabriel*, Franz Dietrich**, Klaus Dröder***

*TU Braunschweig, Institute of Machine Tools and Production Technology, Germany, **TU Braunschweig, Institute of Machine Tools and Production Technology, Germany, ***TU Braunschweig, Institute of Machine Tools and Production Technology, Germany

ABSTRACT

Research on soft material robotic systems has recently increased, since soft robots offer a rich potential for application in human-robot collaboration, surgical applications or search-and-rescue operations. In contrast to rigid robots, the task-specific design of soft robots highly depends on the available materials, actuation control and manufacturability. There is a significant body of work about mathematical representations of the robot motion and control, in order to determine task-optimized designs. The manufacturing of such designs is mostly considered in a subsequent stage, so that a sequential methodology evolves. This sequential procedure causes that function is prioritized over manufacturability. It is the intention to equalize this asymmetry in order to access previously unconsidered yet competitive design structures. This challenge is approached by the aggregation of a joint task-oriented and manufacturing-oriented design methodology. In such an aggregated methodology, it is straightforward to include monolithic material, gradient material and multi-material manufacturing processes. The multi-material concept is particularly attractive if the manufacturing sequence comprises the incremental application of pre-produced elements. This significantly reduces the manufacturing effort, even if the functional structure is complex. In order to elaborate a generic solution, this concept schedules finite element modeling such multi-material manufacturing processes and contributes methods to transform these models into function-oriented models for a joint development methodology. The proposed framework comprises the elaboration of two distinct methodology aggregations and their competitive comparison. Both methodologies are parameterized by a user-defined task specification towards which their function and manufacturing optimization algorithms iterate the robot design and its manufacturing plan. The goal is to implement a fully automated development framework, which connects evolutionary optimization algorithms to finite element simulations that represents both material and geometry as well as applied manufacturing procedures. In further research, a case study is intended to be carried out, where robots for a feeding task in a production scenario are developed, manufactured and characterized experimentally. For this case study, a novel design and binary actuation concept for soft robot is proposed, which is distinguished by separation of an actuated internal structure and a passive outer shell. The findings of this case study are then fed back to refine the joint development methodologies. This case study is used for the methodology comparison and to derive practical implications. Ultimately, this supports a decision about the superior methodology to be deployed further in the future.

ABSTRACT

Osteoporotic changes lead to future low-energy fractures. The early detection of them may allow to introduce the treatment preventing many potential patients from fractures. The development of new diagnostic methods for osteoporotic changes, providing supplementary information to the routine screening tests like densitometry, would improve the accuracy of a diagnosis by more effective prediction of bone strength properties. Osteoporosis caused destruction of the trabeculae in the cancellous part of the vertebra body. Numerous researches shown the strong relation between the trabeculae architecture and the bone strength [1-2]. These reports explain the cause of a bone destruction in osteoporotic fractures, but due to a low spatial resolution of the clinical computed tomography (CT), it is not possible to implement the trabecula quantitative description as a method of a diagnosis for the osteoporotic changes. Presented study attempted to evaluate the impact of a shape of a vertebra body and the thickness of a cortical wall of the vertebra body on its stiffness. The cortical well visible on clinical CT images that may be used for the analysis by physicians thus it is considered as a potential complementary feature for the diagnostic purpose. The performed study was based on the image of a three-dimensional human vertebra obtained from a X-ray computed microtomographic (?CT) study, clinical CT and the compression test of the vertebra. Histomorphological features of the trabeculae structure were calculated from the ?CT. Clinical CT images of vertebrae were used to design simplified geometrical model for a simulation of the compressive test employing the final elements method (FEM). The simulation of the compression test with different materials characteristic and properties, using the material characteristic of healthy bone, osteoporotic bone, and compare the result to the experimental data were performed. Obtained results of simulation were compared to the results from the real experimental compression tests of vertebrae. Finally, statistical analysis were performed, to identify the impact of all considered parameters on the stiffness. References 1. Multi-scale Modelling of the Mechanics of Concrete Based on the Cement Paste Properties

Erez Gal*, Gili Sherzer**

*Department of Structural Eng., Ben-Gurion University, **Department of Structural Eng., Ben-Gurion University

ABSTRACT

The mechanical response of concrete is complex and as other composite materials, multiscale modelling has the potential for modeling its macroscopic behavior. This paper presents an upscaling methodology for the model-ling of the concrete mechanical properties. The suggested formulation starts from a known chemical and me-chanical set of parameters of the cement paste, which are used to evaluate the mechanical properties of the LDPM (Lattice Discrete Particle Model) concrete mechanical parameters. The parameters are divided to groups, which are related to different damage modes such as: pore collapse and material compaction, cohesive behavior, and shear behavior. For each group of parameters a set of microscopic simulations are performed to complete the up-scaling methodology.

Abstract. *ecently, the dsorbed atural as ( ) has been identified as the most promising low pressure alternative for storing natural gas. he not attaining the capacity found in li uefied natural gas ( ), but this technology provides a method of storing gas at substantially higher concentration than can be achieved with simple compression ( ) and dismiss the use of refrigeration. ue to the physics of the process, the temperature of the gas increases during the adsorption, hence it decreases the adhesion of molecules in the adsorbent. he same occurs on desorption process when the temperature of the gas decreases turning it more difficult the release of the gas. Under such circumstances, it seems substantially advantageous to investigate optimum solutions to those systems, but to find them, it is necessary to evaluate sensitives of the control parameters. In particular, on ma ing use of so called d oint Method, it combines shape and parametric optimi ation capabilities one could potentially tac le the full breadth of the problem. ver the years, this method has proven to be a powerful tool for find sensitives in complex systems, where a high fidelity representation of the physics is essential. It has shown to be particularly suitable to tac le problems with large numbers of control parameters, and several possibilities of optimum criteria. o explore the method s potential, numerical transient axi symmetric simulations will be carried out by using a finite element platform FreeFEM considering that the flow is governed by avier Stokes equations ruled by Darcy's law. The Adjoint equations, which were derived from the flow physics, were also implemented in the same platform. he presentation of the article will consist in a description of d oint Method, followed by the mathematical model and validation tests, showing the reduction of the computation cost to evaluate sensitivities hen, the conclusion of the wor and the next steps of the research.*

1 INTRODUCTION

Worldwide, the energy market is going through a phase of intense research and development efforts. In several countries, the energy matrices are undergoing progressive changes, so as to adapt to more stringent environmental laws and to the global economy instabilities. In this scenario, the Natural Gas appears as a source of energy of growing relevance, owing to both its direct uses and to the possibilities, it offers regarding the process of gas reform, for hydrogen production and carbon capture. The growth of its share of the energy market prompts the need to optimize the chain of production, processing and storage of Natural Gas. The search for optimal solutions should allow significant savings.

Amongst the most relevant approaches to optimization, the Adjoint Method stands out as it allows an exceptional reduction in the computational costs of design sensitivity derivatives, requirement to optimization methods. The method is also attractive for its high fidelity to the flow physics, and for the great diversity of its applications. This article presents the use the Adjoint Method to find non-geometric sensitivities in Natural Gas Adsorption Systems for storage, known by the abbreviation ANG.

2 PROBLEM DESCRIPTION

2.1 Adsorption

The Adsorption is defined as the adhesion of molecules in an extremely thin layer (as of gases, solutes or liquids) to the surfaces of solid bodies or liquids with which they are in contact. It can be classified either as physical adsorption or as chemical adsorption depending on the occurrence of reactions. In this work, we are only interested in the physical adsorption phenomenon, particularly in a gas-solid interaction. Physical adsorption is caused mainly by the van der Waals force and electrostatic forces between adsorbate (gas) molecules and the atoms which compose the adsorbent (solid) surface [1,2].

2.2 ANG Technology

The ANG systems consists in a simple tank (cylindrical or not), filled by an adsorbent (activated carbon, for example). A basic scheme of the ANG tank is presented below:

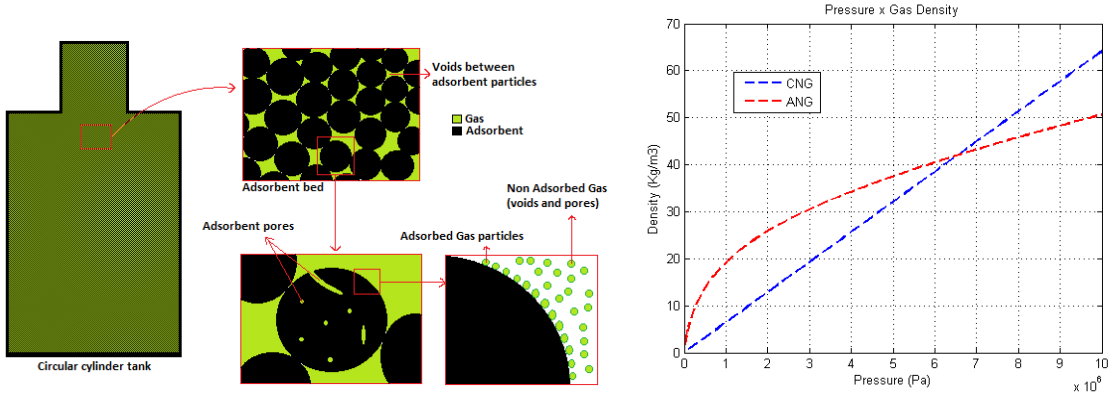

Figure 2. Left: Scheme of ANG Tank. Right: Density comparison between CNG and ANG systems at 300 K

Observing the fig.2 on the left, during the filling process, the gas can be stored in two places: i) In the spaces between the adsorbent particles and in the pores spaces, that they are considered in mathematical model only as "voids" and ii) Close to the adsorbent surfaces, that it considered as "adsorbed gas".

As mentioned in the Introduction, the method provides a means of storing gas at substantially higher concentration than can be achieved with CNG at the same pressure [3]. Using a quantitative example, the fig. 2 on the right presents a simple comparison between the gas density (using a standard activated carbon as adsorbent) for different pressures. Also in this figure, it is clear that for a certain range of pressures, the ANG systems could store more gas than CNG at the same pressure, considering the isothermal process. In this example, using a particular adsorbent, the differences achieve 44% at 3.5MPa and exceed 100% at low pressures, close to 1.5 MPa. However, above to 6.5 MPa, the density in CNG system overtakes that ANG with standard activated carbon adsorbent.

3 FLOW PHYSICS

The governing equations are presented below, where the main assumptions are: Pure NG (100% Methane as ideal gas); properties of the adsorbent bed are constant and the bed is considered isotropic with spherical particles and homogenous pores distribution [4]. The equations were nondimensionalized, to avoid bad conditioning of matrices that are used to solve the flow equations numerically. The nondimension state equation $p = \rho_g . T$ were plug in the equations and the result is presented as follows:

$$\epsilon_t \left(\frac{1}{T}.\frac{\partial p}{\partial t} + \frac{p}{T^2}.\frac{\partial T}{\partial t}\right) + \rho_b \frac{\partial q}{\partial t} + \nabla.\vec{G} = 0 \quad (1)$$

$$\vec{G} + N_p \rho_g \nabla p = 0 \quad (2)$$

$$C_{eff}\frac{\partial T}{\partial t} - \epsilon_t \left(\frac{\gamma-1}{\gamma}\right)\frac{\partial p}{\partial t} + \nabla.\left(\vec{G}.T\right) - \frac{1}{Pe}\nabla^2 T - \frac{\rho_b \Delta H}{M_g}.\frac{\partial q}{\partial t} = 0 \quad (3)$$

$$q = \rho_{ads}.W_0.exp\left[-\left(\frac{A}{\beta E_0}\right)^n\right] \quad (4)$$

Eq.(1) is the continuity equation where ϵ_t is the total porosity of adsorbent bed (no-dimensional); ρ_b is the density of adsorbent bed; q is defined as the density of adsorption, eq. (4), $\vec{G} = \rho_g \vec{u}$ is the specific mass flux vector, where ρ_g is the free gas density (located in the voids between particles and in the respective pores) [5].

Eq.(2) are the momentum equation with Darcy law simplifications, where ∇p is the pressure gradient; $N_p = \frac{K\rho_\infty}{\mu l_{ref} v_\infty}$ is the pressure number, defined in terms of μ (gas viscosity), K (permeability of the adsorbent bed, [4]), and the reference values of adimensionalization, $\rho_\infty, l_{ref}\ and\ v_\infty$.

Eq. (3) is the Energy equation, where $C_{eff} = \left(\epsilon_t \rho_g + \rho_b q\right)C_{pg} + \rho_b C_{ps}$, which C_{pg} and C_{ps} represents the specifics heat of gas and adsorbent respectively; $P_e = \frac{\rho_\infty C_{pg} v_\infty l_{ref}}{\lambda_{ref}}$ is the Péclet number; $\lambda_{eff} = \epsilon_t.\lambda_g + (1-\epsilon_t)\lambda_s$ is the effective thermal conductivity in terms of porosity and thermal conductivity of gas(λ_g) and adsorbent (λ_s), ΔH is the heat of adsorption which is assumed constant and M_g is the molar mass of the gas.

Finally, eq. (4) is the Dubinin-Astakov (DA) model [4,5], where ρ_{ads} is the adsorbed gas density, defined by: $\rho_{ads} = \frac{\overline{\rho_{ads}}}{\exp[\alpha_e(T-T_b)]}$, where $\overline{\rho_{ads}}$ is the density of liquid phase of the adsorbed fluid in the saturation region, T_b is the gas boiler temperature and α_e is the mean value of the thermal expansion of the liquefied gas. W_0 is the microporous volume per unit mass of adsorbent, β is the coefficient related to the gas-solid interaction, E_0 is the characteristic adsorption energy, and n is the DA exponent which is related to the pore size dispersion. $A = RTln\left(\frac{P_s}{P}\right)$ is the so-called as Polany adsorption potential: where $P_s = P_{cr}\left(\frac{T}{T_{cr}}\right)^2$.

4 NUMERICAL IMPLEMENTATION

The equations were implemented in *FreeFEM* platform [7]. This software is a high level integrated development environment for numerically solving partial differential equations in 2 and 3 dimensions. To simulate the previous equations, it is necessary to define geometry, mesh and a set of boundary conditions:

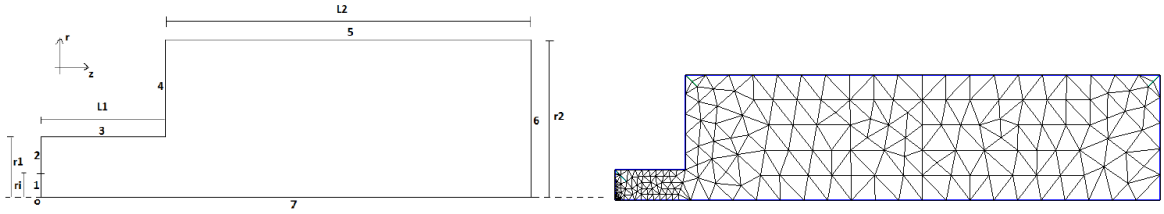

Figure 3. Left: Schematic of a 2D axi-symmetric ANG Storage System – The point "o" represents the origin of coordinate system. Right: Mesh implemented by FREEFEM++ platform

Boundary	Conditions
Inflow (1): Parabolic mass flux in the axial direction. t_{ac} is the time when the nominal mass flux is achieved.	$G_z = \begin{cases} 2\rho_0 u_{in}\left(1-\frac{r^2}{r_i^2}\right)\left(\frac{t}{t_{ac}}\right), if\ t < tac \\ 2\rho_0 u_{in}\left(1-\frac{r^2}{r_i^2}\right), if\ t \geq tac \end{cases}$, $G_r = 0$, $T = T_{in}$
Wall (2 - 6): No slip boundary condition with heat transfer	$G_z = 0$, $G_r = 0$, $-n.\nabla T = N_u(T - T_{ext})$
Symmetry (7): Since the symmetry axis is parallel to z axis, the condition, $\vec{G}.\vec{n} = 0$ reduces to $G_r = 0$.	$G_r = 0$ $n.\nabla T = 0$

Table 1 – Set of Boundary Conditions

Where ρ_0 is the gas density in the inlet; u_{in} is the velocity based on volumetric flow rate at STP; T_{ext} is the ambient temperature and N_u is the Nusselt number defined as $N_u = \frac{h.l_{ref}}{\lambda_{eff}}$. The studies of mesh sensitivity, validation tests and exploratory simulations were published in previous works [7,8] and the following figures shows some results as example. This test verified the influence of the heat transfer coefficient at the tank walls. The Nusselt number affected directly the density of gas adsorbed and the understanding the sensitivity of this parameter could be essential to increase the tank capacity. The Adjoint method presented in the next section were implemented to find the sensitivity of this parameter.

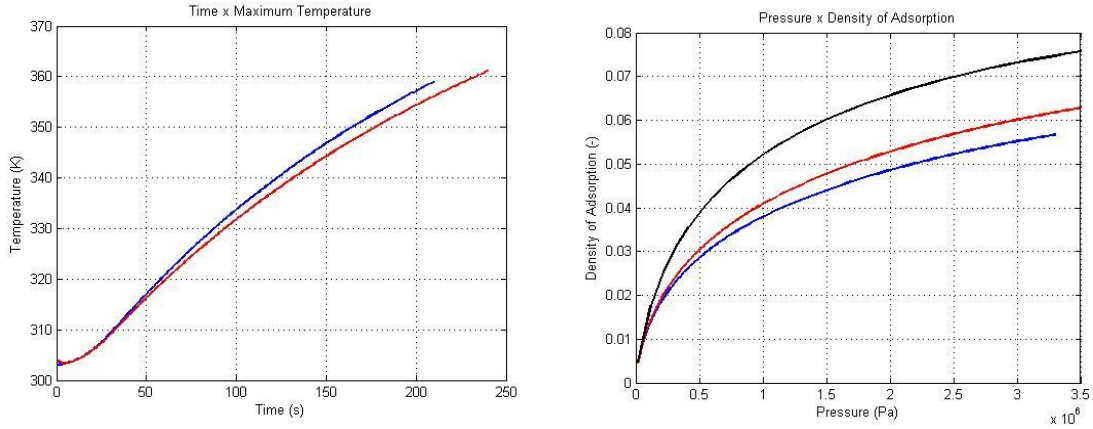

Figure 5. Left: Maximum Temperature inside the tank during the filling process. Right: Evolution of Density of Adsorption (q) during the filling process. Black: Isorthermal process (ideal); Blue: Natural Convection in tank walls; Red: Forced Convection in the tank walls [7,8].

INTRODUCTION TO THE ADJOINT METHOD

Historically, the Adjoint Method has evolved into two distinct approaches: discrete and continuous. In the former, a discrete Adjoint operator is obtained on the basis of already discretized flow governing equations. Whereas in the latter case, the Adjoint equations are derived analytically from the equations that govern the physics, and only then, they are discretized [9]. Comparisons between the two approaches have also been drawn in the literature [10,11,12], and they do not indicate any sizable differences between them.

This article adopted the so–called continuous formulation of the Adjoint method as it is more directly in line with our approach to the Adjoint boundary problem. As an additional result of this choice, the numerical methods that were used to integrate the primal problem (flow physics) are independent of those that are applied to the dual (Adjoint), thereby making the flow and Adjoint solvers fully independent, as well.

In essence, the Adjoint method is a powerful tool to compute the sensitivity of a given measure of merit, with respect to any number of parameters that control the boundary conditions of a physical system. That system is assumed to be governed by a set of Partial Differential Equations, and the measure of merit is taken to be an objective functional. In any case, the integration boundaries, and the boundary conditions, themselves, are controlled by a set of design parameters. Under these circumstances, a natural means of estimating the sensitivity of

a functional to changes in flow parameters, would be to perturb each one of them individually, and then to compute the sensitivity gradient by central finite differences.

The procedure clearly requires two converged flow solution for each parameter variation. As the number of design parameters increases, the computational cost is bound to become prohibitive. Alternatively, by imposing the flow equations as constraints to the optimization of objective function, one precludes unrealizable solutions. That, in turn, eliminates the need for additional simulations. That is the essence of the Adjoint Method which sensitivity gradient need only 2 solutions, independently of the number of design parameters.

THE ADJOINT METHOD APPLIED IN FLOWS THOUGH POROUS MEDIA

This section is dedicated to the Adjoint problem, as it applies to the particular class of flows that is the interest in this work. It discusses the derivation of the Adjoint equations, along with their boundary and time conditions. Throughout the deduction, the references which guided the results were mentioned and it is recommended to read to deepen the theoretical basis of the method. We start by considering a measure of merit of a given physical system:

$$R[X,\alpha] = \frac{1}{T}\int_0^T \int_D F[X,\alpha] dV\, dt \tag{5}$$

Where F could be any function of the state vector $\mathrm{X} = (\rho, \vec{\mathrm{u}}, \mathrm{T})$ and the project parameters $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_n)$. The first Gateaux variation [16] of the functional yields the expression:

$$\delta \mathrm{R} = \langle \mathrm{F}_{\mathrm{x}}^{'}, \delta \mathrm{X} \rangle + \langle \mathrm{F}_{\alpha}^{'}, \delta\alpha \rangle \tag{6}$$

Where $\langle \mathrm{a}(\nu), \mathrm{b}(\nu) \rangle = \frac{1}{\mathrm{T}}\int_0^{\mathrm{T}} \int_{\mathrm{D}} \mathrm{a}(\nu).\mathrm{b}(\nu) \mathrm{dV}\, \mathrm{dt}$ represents the inner product defined in the phase space and on the appropriate boundaries of the domain. In general, the term $\langle \mathrm{F}_{\alpha}^{'}, \delta\alpha \rangle$ is known in closed form and, thus, the variation can be evaluated analytically. The greatest difficulty in estimating $\delta \mathrm{R}$ lies in $\delta \mathrm{X}$ in the first term, $\langle \mathrm{F}_{\mathrm{x}}^{'}, \delta \mathrm{X} \rangle$, instead. To eliminate the necessity of additional converged solutions to estimate $\langle \mathrm{F}_{\mathrm{x}}^{'}, \delta \mathrm{X} \rangle$, the governed equations were imposed as constrains, using Lagrange multipliers, defining, the augmented functional:

$$G[X,\alpha] = R[X,\alpha] - \langle \Phi, \mathrm{L} \rangle - \langle \beta, \mathrm{B} \rangle_s - \langle \mathrm{a}, \alpha - \alpha_0 \rangle_s \tag{7}$$

Where $\Phi = (\omega, \vec{\Psi}, \theta)$ are the Lagrange multipliers. L represents a operator vector which components are the eqs. (1-3). β is the multiplier for the set of the Boundary conditions and **a** is the constraint that ensures that the control parameters take on a given set of prescribed values $\alpha = \alpha_0$, which corresponds to a baseline configuration. Computing the variations and make a suitable combination, the first variation of augmented functional δG is [8]:

$$\begin{aligned} \delta G[X,\alpha] = &-\langle \delta\Phi, L \rangle - \langle \delta\beta, B \rangle_s - \langle \delta a, \alpha - \alpha_0 \rangle_s + \langle L^*\Phi + F_x', \delta X \rangle - \langle \beta, B'_x \delta X \rangle_s - \\ &\langle P_1(\Phi), B_x' \delta X \rangle_s - \langle B^*(\Phi), A\delta X \rangle_s + \langle F_\alpha^{'}, \delta\alpha \rangle - \langle \mathrm{a}, \delta\alpha \rangle - \langle \beta, B'_\alpha \delta\alpha \rangle \end{aligned} \tag{8}$$

Where the eq.(6) has been replaced in eq.(8). The Gauss´s theorem is used to transfer differential operators from the state vector X to the Lagrange multipliers:

$$\langle \Phi, L\delta X \rangle = P[\Phi, \delta X]_s - \langle \mathrm{L}^*\Phi, \delta X \rangle \tag{9}$$

Where the term $P[\Phi, \delta X]_s = [\langle P_1(\Phi), B'_x \delta X \rangle_s + \langle B^*(\Phi), A\delta X \rangle_s]$ is the bilinear concomitant [14]. The augmented functional G realizes extrema upon the condition that eq. (8) vanishes for arbitrary, albeit realizable, variations of its parameters:

$$\delta G = 0 \; \forall \{\delta X, \delta\alpha, \delta\Phi, \delta\beta, \delta a\} \, \epsilon \, \{locus \; of \; realizability\}$$

That, in turn, requires that the following conditions be met [14]:

a) The equations that govern the physics (1-4) and their respective boundary conditions (table 1) are satisfied. In addition, the control parameters should take on the prescribed baseline values ($\alpha = \alpha_0$). These requirements imply that first three terms of eq. (12) are identically zero.
b) On imposing the condition: $\beta = -P_1(\Phi)$, one drives to zero the sum of the fifth and sixth terms of eq. (8).
c) The vector Φ must satisfy the Adjoint equation, $L^*\Phi + F'_x \delta X = 0$, as it appears in the fourth term of eq.(8). The corresponding boundary conditions are given by the operator: $B^*(\Phi) = 0$, which comes from the seventh term in that equation. This equation should determine the Φ at the boundaries, along with β thereof.
d) The vector **a** is specified by the following condition: $\langle \mathrm{a}, \delta\alpha \rangle = \langle F'_\alpha, \delta\alpha \rangle + \langle \Phi, \mathrm{S}\delta\alpha \rangle - \langle \beta, B'_\alpha \delta\alpha \rangle = \langle F'_\alpha, \delta\alpha \rangle + \langle P_1(\Phi), B'_\alpha \delta\alpha \rangle$, which collects all the remaining terms when $\delta G = 0$. In fact, this is the realizable part of the gradient, δR [8]:

$$\delta R = \langle F'_\alpha, \delta\alpha \rangle + \langle P_1(\Phi), B'_\alpha \delta\alpha \rangle \tag{10}$$

ADJOINT E UATIONS

This section is dedicated to applying the flow governing equations in the fourth term of eq. (8). Using the independence between the primal and dual problem, we make of the simplest form of the governing equations. It yields:

$$\begin{aligned} \langle \Phi, LX \rangle = \langle \omega, \epsilon_t \, \partial_0 \rho + \; \rho_b \, \partial_0 q + \nabla \rho \vec{u} \rangle + \langle \overrightarrow{\Psi}, \vec{u} + N_p \nabla p \rangle \\ + \langle \theta, \partial_0 \left[C_{eff} T - \epsilon_t \left(\frac{\gamma - 1}{\gamma} \right) P \right] + \nabla \rho \vec{u} T - \frac{1}{Pe} \nabla^2 T - \frac{\rho_b \Delta H}{M} \partial_0 q \rangle \end{aligned} \tag{11}$$

Where $\partial_0 = \frac{\partial}{\partial t}$. Computing the Gateaux variations:

$$\begin{aligned} \langle \Phi, L\delta X \rangle = \langle \omega, \epsilon_t \, \partial_0 \delta\rho + \; \rho_b \, \partial_0 \delta q + \nabla(\delta\rho \vec{u} + \rho \delta\vec{u}) \rangle + \langle \overrightarrow{\Psi}, \delta\vec{u} + N_p \nabla \delta p \rangle \\ + \langle \theta, \partial_0 \left[\delta C_{eff} T + C_{eff} \delta T - \epsilon_t \left(\frac{\gamma - 1}{\gamma} \right) \delta P \right] + \nabla(\delta\rho \vec{u} T + \rho \delta\vec{u} T + \rho \vec{u} \delta T) \\ - \frac{1}{Pe} \nabla^2 \delta T - \frac{\rho_b \Delta H}{M} \partial_0 \delta q \rangle \end{aligned} \tag{12}$$

Now, it is necessary to transfer the time and differential operators. To the first, we make use of the rule for differentiating a product. The terms of mass and energy equations become:

$$\langle \omega, \epsilon_t \, \partial_0 \delta\rho + \; \rho_b \, \partial_0 \delta q \rangle = \left[\frac{1}{T} \oint \omega (\epsilon_t \delta\rho + \; \rho_b \delta q) dV \right]_0^T - \langle \partial_0 \omega, \epsilon_t \delta\rho + \; \rho_b \delta q \rangle \tag{13}$$

$$\begin{aligned} \langle \theta, \partial_0 \left[\delta C_{eff} T + C_{eff} \delta T - \epsilon_t \left(\frac{\gamma - 1}{\gamma} \right) \delta P - \frac{\rho_b \Delta H}{M} \delta q \right] \rangle = \left[\frac{1}{T} \oint \theta \left(\delta C_{eff} T + C_{eff} \delta T - \right. \right. \\ \left. \left. \epsilon_t \left(\frac{\gamma - 1}{\gamma} \right) \delta P - \frac{\rho_b \Delta H}{M} \delta q \right) dV \right]_0^T - \langle \partial_0 \theta, \left[\delta C_{eff} T + C_{eff} \delta T - \epsilon_t \left(\frac{\gamma - 1}{\gamma} \right) \delta P - \frac{\rho_b \Delta H}{M} \delta q \right] \rangle \end{aligned} \tag{14}$$

The terms $\left[\frac{1}{T} \oint (\ldots) \right]_0^T$ were driven to zero because at $t = 0$, the flow solution is known and its variations δX are zero. Additionally, we impose a final condition of the Adjoint problem, by imposing that they vanish ($\omega = \theta = 0$ and $\overrightarrow{\Psi} = \vec{0}$) at $t = T$ [14]. To transfer the differential

operators, the Gauss´s theorem was applied in convective terms, gradient pressure and diffusive term of the energy equation as follows:

$$\langle \omega, \nabla(\delta\rho\vec{u} + \rho\delta\vec{u})\rangle = \langle \omega, (\delta\rho\vec{u} + \rho\delta\vec{u}).\vec{n}\rangle_s - \langle \nabla\omega, (\delta\rho\vec{u} + \rho\delta\vec{u})\rangle \quad (15)$$

$$\langle \theta, \nabla(\delta\rho\vec{u}T + \rho\delta\vec{u}T + \rho\vec{u}\delta T)\rangle = \langle \theta, (\delta\rho\vec{u}T + \rho\delta\vec{u}T + \rho\vec{u}\delta T).\vec{n}\rangle_s - \langle \nabla\theta, \nabla(\delta\rho\vec{u}T + \rho\delta\vec{u}T + \rho\vec{u}\delta T)\rangle \quad (16)$$

$$\langle \overrightarrow{\Psi}, N_p\nabla\delta p\rangle = \langle \overrightarrow{\Psi}.\vec{n}, N_p\delta p\rangle_s - \langle \nabla.\psi^{\mathrm{i}}, N_p\delta p\rangle \quad (17)$$

$$\langle \theta, -\tfrac{1}{Pe}\nabla^2\delta T\rangle = \langle \theta, -\tfrac{1}{Pe}\nabla\delta T.\vec{n}\rangle_s - \langle \nabla\theta, -\tfrac{1}{Pe}\nabla\delta T\rangle = \langle \theta, -\tfrac{1}{Pe}\nabla\delta T.\vec{n}\rangle_s - \langle \nabla\theta.\vec{n}, -\tfrac{1}{Pe}\delta T\rangle + \langle \nabla^2\theta, -\tfrac{1}{Pe}\delta T\rangle \quad (18)$$

The four terms with subscript "s" form the bilinear concomitant. Using the relations: $\delta p = \delta\rho T + \rho\delta T, \delta q = A_\rho\delta\rho + A_T\delta T,\ \delta C_{eff} = (\epsilon_t + \rho_b A_\rho)\delta\rho + (\rho_b A_T)\delta T,\ \sigma = \omega - \theta T$ and combine the terms, the Adjoint equations yield:

$$\langle \delta\rho, \Gamma_{11}\partial_0\sigma + \Gamma_{12}\partial_0\theta + \Gamma_{13}\nabla\sigma + \Gamma_{14}\nabla.\overrightarrow{\Psi} + \Gamma_{15}\theta\rangle = \langle F'_\rho\delta\rho\rangle \quad (19)$$

$$\langle \delta\vec{u}, \Gamma_{21}\overrightarrow{\Psi} + \Gamma_{22}\nabla\sigma + \Gamma_{23}\theta\rangle = \langle F'_{\vec{u}}, \delta\vec{u}\rangle \quad (20)$$

$$\langle \delta\mathrm{T}, \Gamma_{31}\partial_0\sigma + \Gamma_{32}\partial_0\theta + \Gamma_{33}\nabla\theta + \Gamma_{34}\nabla.\overrightarrow{\Psi} + \Gamma_{35}\theta + \Gamma_{36}\nabla^2\theta\rangle = \langle F'_T\delta T\rangle \quad (21)$$

Where:

$\Gamma_{11} = (\epsilon_\mathrm{t} + \rho_b A_\rho)$	$\Gamma_{12} = \left[-\epsilon_t\left(\frac{\gamma-1}{\gamma}\right)T - \frac{\Delta H}{M}\rho_b A_\rho\right]$	$\Gamma_{13} = \vec{u}$
$\Gamma_{14} = N_p T$	$\Gamma_{15} = -[(\epsilon_t + \rho_b A_\rho)\partial_o T + \vec{u}\nabla T]$	
$\Gamma_{21} = -1$	$\Gamma_{22} = \rho$	$\Gamma_{23} = -\rho\nabla T$
$\Gamma_{31} = \rho_b A_T$	$\Gamma_{32} = \left[C_{eff} - \epsilon_t\left(\frac{\gamma-1}{\gamma}\right)\rho - \frac{\Delta H}{M}\rho_b A_T\right]$	$\Gamma_{33} = \rho\vec{u}$
$\Gamma_{34} = N_p\rho$	$\Gamma_{35} = -(\rho_b A_T)\partial_o T$	$\Gamma_{36} = -\frac{1}{Pe}$
$A_\rho = -\frac{qD_1 T}{\rho}$	$A_T = q[D_1(D_2+1) - \alpha_e]$	$D_1 = C_2 n(TD_2)^{n-1}$
$D_2 = \left[ln\left(\frac{C_3 T^2}{p}\right)\right]$	$C_2 = -\left(\frac{R}{\beta E_0}\right)^n$	$C_3 = \frac{p_{cr}}{T_{cr}^2}$

Table 2 – Coefficients of Adjoint Equations

The bilinear concomitant becomes:

$$P[\Phi, \delta X]_s = \langle \sigma, (\delta\rho\vec{u} + \rho\delta\vec{u}).\vec{n}\rangle_s + \langle \overrightarrow{\Psi}.\vec{n}, (\delta\rho\mathrm{T} + \rho\delta\mathrm{T})\rangle_s + \langle \theta, \left(\rho\delta\mathrm{T}\vec{u}.\vec{n} - \tfrac{\nabla\delta T.\vec{n}}{Pe}\right)\rangle_s + \langle \nabla\theta.\vec{n}, \tfrac{\delta T}{Pe}\rangle_s \quad (22)$$

Where the terms were divided into 2 parts, where $P_1(\Phi)$ are related to linearized boundary conditions, $B'_x\delta X$ and $B^*(\Phi)$ which represents the Adjoint Boundary conditions:

BC	Flow	Flow Lineari ed	Ad oint
Inlet	$\rho\vec{u} - f(X,t,G_m) = 0$ $T - T_{in} = 0$	$(\delta\rho\vec{u} + \rho\delta\vec{u}) - \frac{\partial f}{\partial G_m}\delta G_m - \frac{\partial f}{\partial t_{ac}}\delta t_{ac} = 0$ $\delta T - \delta T_{in} = 0$	$\overrightarrow{\Psi}.\vec{n} = 0$ $\theta = 0$
Outflow	$P - P_{out} = 0$	$(\delta\rho\mathrm{T} + \rho\delta\mathrm{T}) - \delta P_{out} = 0$	$\sigma = 0$

			$\nabla\theta.\vec{n} = -(Pe\rho\vec{u}.\vec{n})\theta$
Wall	$\rho\vec{u} = 0$ $-\nabla T.\vec{n} = \mathrm{Nu}(T - T_{ext})$	$(\delta\rho\vec{u} + \rho\delta\vec{u}) = 0$ $-\nabla\delta T.\vec{n} = \delta\mathrm{Nu}(T - T_{ext}) + Nu\delta T - Nu\delta T_{ext} = 0$	$\vec{\Psi}.\vec{n} = 0$ $\nabla\theta.\vec{n} = \mathrm{Nu}\theta$
Sym.	$\rho\vec{u}.\vec{n} = 0$ $\nabla T.\vec{n} = 0$	$(\delta\rho\vec{u} + \rho\delta\vec{u})\vec{n} = 0$ $\nabla\delta T.\vec{n} = 0$	$\vec{\Psi}.\vec{n} = 0$ $\nabla\theta.\vec{n} = 0$

Table 3 – Flow and Adjoint Boundary Conditions

Where $G_m = \rho_0 \mathrm{u_{in}}$, T_{in}, $\mathrm{N}u$ and T_{ext} represents the average mass flux vector, inlet temperature, Nusselt number and ambient temperature respectively. These terms can be used as design parameters in the validation tests. The outflow pressure, P_{out} was not tested because the status of the research archived only the process of the filling in ANG tanks.

VALIDATION TESTS

The objective of the validation tests was to prove the reduction of the computational cost if the Adjoint Method is used to estimate the sensibility gradient. As previously mentioned, the centered finite differences was used as reference, considering it as the simplest method to evaluate sensitives. The expression of this method is presented below:

$$\frac{\partial R}{\partial \alpha_p} = \frac{R(\alpha_1,\alpha_2,\dots,\alpha_p+\delta\alpha_p,\dots,\alpha_n) - R(\alpha_1,\alpha_2,\dots,\alpha_p-\delta\alpha_p,\dots,\alpha_n)}{2\delta\alpha_p} \tag{23}$$

Where $R(\alpha_1, \alpha_2, \dots, \alpha_p + \delta\alpha_p, \dots, \alpha_n)$ and $R(\alpha_1, \alpha_2, \dots, \alpha_p - \delta\alpha_p, \dots, \alpha_n)$ are the measure of merit (objective function) evaluated for a positive $(+\delta\alpha_p)$ and negative $(-\delta\alpha_p)$ perturbation of design parameter α_p. These terms were evaluated using a respective numeric solution of the flow governing equations (1-4). The tests were done using two objective functions: Volumetric Average Pressure and Volumetric Average Temperature. The design parameters were four G_m, t_{ac}, $\mathrm{N}u$ and T_{ext}.

9.1 Volumetric Average Pressure

Using this variable as objective function, the eqs (5-6) were determined. Using the non dimensional ideal gas state equation ($p = \rho T$):

$$R[(\rho, \vec{u}, T), (G_m, Nu, T_{ext})] = \frac{1}{T}\int_0^T \int_D \frac{p}{V_t}\, dV\, dt \tag{24}$$

$$\delta\mathrm{R}[(\rho, \vec{u}, T), (G_m, Nu, T_{ext})] = \langle\frac{\mathrm{T}}{\mathrm{V_t}}, \delta\rho\rangle + \langle\frac{\rho}{\mathrm{V_t}}, \delta\mathrm{T}\rangle \tag{25}$$

Where V_t is the geometric volume of the tank, $\langle F'_{\rho}\delta\rho\rangle = \langle\frac{\mathrm{T}}{\mathrm{V_t}}, \delta\rho\rangle$, $\langle F'_{\vec{u}}\delta\vec{u}\rangle = 0$, $\langle F'_{T}\delta T\rangle = \langle\frac{\rho}{\mathrm{V_t}}, \delta\mathrm{T}\rangle$ and $\langle F'_{\alpha}, \delta G_m\rangle = \langle F'_{\alpha}, \delta Nu\rangle = \langle F'_{\alpha}, \delta T_{ext}\rangle = 0$. With the solutions of the Flow and Adjoint equations and collecting the remaining terms of the bilinear concomitant, the sensitivity gradient yields:

$$\delta R = \left\langle \begin{cases} 2\sigma\left(1-\frac{r^2}{r_i^2}\right)\left(\frac{t}{t_{ac}}\right).\vec{n}, if\ t < tac \\ 2\sigma\left(1-\frac{r^2}{r_i^2}\right).\vec{n} \quad , if\ t \geq tac \end{cases}, \delta G_m \right\rangle + \left\langle \begin{cases} 2\sigma\rho_0 u_{in}\left(1-\frac{r^2}{r_i^2}\right)\left(-\frac{t}{t_{ac}^2}\right).\vec{n} \ , if\ t < tac \\ 0 \quad , if\ t \geq tac \end{cases}, \delta t_{ac} \right\rangle + \left\langle \frac{\theta(T-T_{ext})}{Pe}, \delta Nu \right\rangle + \left\langle -\frac{\theta Nu}{Pe}, \delta T_{ext} \right\rangle \quad (26)$$

The four terms of δR represent the components of the sensitivity gradient, each one in terms of the respective control parameter. The tests were performed simulating a filling process, with volumetric flow of 15 LPM at STP. The geometric and adsorbent parameters were the same of the presented in [4]. The total physical time was 210s and the sensitivity gradient were estimated in three points (90, 150 and 210s). The results are presented as follows:

$\frac{\partial R}{\partial Gm}$	Adjoint	Finite Difference	Dif. (%)	$\frac{\partial R}{\partial tac}$	Adjoint	Finite Difference	Dif. (%)
s	9.561e-02	9.737e-02	-1.81%	**s**	-9.019e-03	-9.134e-03	-1.25%
1 s	2.892e-01	2.916e-01	-0.81%	**1 s**	-1.482e-02	-1.481e-02	+0.09%
21 s	6.056e-01	6.058e-01	-0.05%	**21 s**	-2.107e-02	-2.080e-02	+1.34%

Table 4 – Results for two sensitivity gradient components for average pressure, G_m and t_{ac}

$\frac{\partial R}{\partial Nu}$	Adjoint	Finite Difference	Dif. (%)	$\frac{\partial R}{\partial T_{ext}}$	Adjoint	Finite Difference	Dif. (%)
s	-1.967e-04	-1.962e-04	0.28%	**s**	2.097e-01	2.091e-01	0.28%
1 s	-9.103e-04	-9.061e-04	0.47%	**1 s**	6.329e-01	6.300e-01	0.45%
21 s	-2.510e-03	-2.495e-03	0.58%	**21 s**	1.324e+00	1.317e+00	0.59%

Table 5 – Results for two sensitivity gradient components for average pressure, Nu and T_{ext}

The differences between Adjoint and Finite Differences were very low, corroborating the consistency of the Adjoint equations, boundary conditions and gradient expressions. The components in terms of Adjoint variable θ (Nu, T_{ext}), obtained small differences than components in terms of σ (G_m, t_{ac}).

Moreover, the computational cost reduced dramatically using the Adjoint Method. Considering a comparison using the results at $t = 210s$, the cost of one numeric flow simulation, using an ordinary computer was approximately 45 minutes. For each component of gradient estimated by Finite Difference Method, the cost was 2 flow simulations, or 1,5h. Then, for estimated the values $\left(\frac{\partial R}{\partial Gm}, \frac{\partial R}{\partial tac}, \frac{\partial R}{\partial Nu}, \frac{\partial R}{\partial T_{ext}}\right) = (6.058.e-01, -2.080e-02, -2.495e-03, 1.317e+00)$ which represents the values extracted from the tables 4 and 5, the computational cost was $4x1.5 = 6h$.

On the other hand, using the Adjoint Method, only two simulations were needed: The primal problem, or the base flow, with the same computational cost of a flow solution (45 minutes), and the dual problem, or the Adjoint solution, which was expected that the cost was approximately the same of the physics problem. However, the results showed a time of

processing in 1 hour and 10 minutes, 55% greater than a simple numeric flow solution. Then, the total cost of Adjoint Method was 1 hour and 55 minutes.

In the other words, to estimate the values $\left(\frac{\partial \mathrm{R}}{\partial \mathrm{Gm}}, \frac{\partial \mathrm{R}}{\partial \mathrm{tac}}, \frac{\partial \mathrm{R}}{\partial \mathrm{Nu}}, \frac{\partial \mathrm{R}}{\partial \mathrm{T_{ext}}}\right) = (6.056\mathrm{e}-01, -2.107\mathrm{e}-02, -2.510\mathrm{e}-03, 1.324\mathrm{e}+00)$, extracted from tables 4 and 5, there was necessary 32% of the computational cost in comparison between the values estimated by Finite Difference Method.

9.2 Volumetric Average Temperature

Using the volumetric Average Temperature as Objetive function, keeping the same control parameters, eq.(30) at previous section, the only changes was in components of $\langle F'_X \delta X \rangle$:

$$R[(\rho, \vec{u}, T), (G_m, Nu, T_{ext})] = \frac{1}{T}\int_0^T \int_D \frac{T}{V_t}\, dV\, dt \tag{27}$$

$$\delta \mathrm{R}[(\rho, \vec{u}, T), (G_m, Nu, T_{ext})] = \langle \frac{1}{\mathrm{V_t}}, \delta \mathrm{T} \rangle \tag{28}$$

Where V_t is the geometric volume of the tank, $\langle F'_\rho \delta\rho \rangle = 0$, $\langle F'_{\vec{u}} \delta\vec{u} \rangle = 0$, $\langle F'_T \delta T \rangle = \langle \frac{1}{\mathrm{V_t}}, \delta \mathrm{T} \rangle$ and $\langle F'_\alpha, \delta G_m \rangle = \langle F'_\alpha, \delta Nu \rangle = \langle F'_\alpha, \delta T_{ext} \rangle = 0$. The results are presented as follows:

$\frac{\partial R}{\partial Gm}$	ADJ	DF	Dif. (%)	$\frac{\partial R}{\partial tac}$	ADJ	DF	Dif. (%)
s	2.309e-03	2.229e-03	3.59%	**s**	-2.528e-04	-2.416e-04	4.64%
1 s	4.079e-03	3.841e-03	6.18%	**1 s**	-2.671e-04	-2.461e-04	8.59%
21 s	5.532e-03	5.093e-03	8.61%	**21 s**	-2.636e-04	-2.346e-04	12.37%

Table 6 – Results for two sensitivity gradient components for average temperature, G_m and t_{ac}

$\frac{\partial R}{\partial Nu}$	ADJ	DF	Dif. (%)	$\frac{\partial R}{\partial T_{ext}}$	ADJ	DF	Dif. (%)
s	-2.4093e-05	-2.407e-05	0.09%	**s**	2.838e-02	2.836e-02	0.02%
1 s	-5.599e-05	-5.589e-05	0.19%	**1 s**	4.421e-02	4.419e-02	0.04%
21 s	-9.644e-05	-9.626e-05	0.19%	**21 s**	5.830e-02	5.824e-02	0.10%

Table 7 – Results for two sensitivity gradient components for average temperature, Nu and T_{ext}

For the components in terms of σ, the results worsened in comparison between the previous result with the pressure as the objective function. On the other hand, the results of components in terms of θ kept suitable regarding the Finite Difference Method. The computational cost had the same advantages of the result with pressure as measure of merit. The cost was 33% of the Finite Difference Method.

1 CONCLUSIONS

This article represents a part of the big project, which objective is to develop a optimization loop to find best solutions of ANG systems, varying not only geometric parameters, but also operational conditions for filling and deflation process, in the other words, a non-geometric parameters. The deduction of Adjoint Method applied in flows through porous media with

adsorption was a success, reducing dramatically the computational cost and make viable the optimization using a great quantity of parameters. There were other results, using different objective functions and control parameters that will be presented in the future.

When the optimization loop is finished, the software will able to make optimal solutions for geometry, filling/deflation time dependent curves, heat transfer using internal and external heat exchanges and others, using only a base flow solution and a Adjoint solution. For conceptual designs, this tool could help the designer to study a great quantity of configurations in a viable time, ensuring a larger probability to find an optimal solution.

Elastic Instabilities and Shear Waves in Soft Composites with Periodic Arrays of Fibers

Pavel Galich*, Viacheslav Slesarenko**, Stephan Rudykh***

*Technion – Israel Institute of Technology, **Technion – Israel Institute of Technology, ***Technion – Israel Institute of Technology

ABSTRACT

Soft fiber composites (FCs), characterized by light weight, high strength and flexibility are widespread in nature. However, natural materials may also carry undesirable properties, such as biodegradability, poor resistance to moisture and/or ultraviolet radiation; hence, manmade composites hold a prominent place in industry. An advantage of nonlinear (soft) composites over linear (hard) composites is high elasticity, allowing significant reversible geometry changes, including buckling; consequently, their effective properties can be tuned by deformation. Specifically, elastic waves in soft composites can be manipulated by deformation (1, 2). It is worth mentioning also that fibrous microstructures are common for various soft biological tissues, which can experience large deformations due to growth or damage, for example. Hence, investigation of elastic wave propagation in deformed FCs can be beneficial for biomedical ultrasound testing, for instance. In this work, we investigate propagation of small amplitude shear waves in marginally stable periodic FCs with rectangular arrays of cylindrical fibers. By utilizing the Bloch-Floquet analysis superimposed on finite macroscopically applied deformations (2, 3), we determine the critical stretches and wavelengths corresponding to the onset of elastic instability in the FCs with rectangular arrays of fibers. In particular, we show that the critical strains for FCs with rectangular arrays of fibers are bounded by the corresponding critical values for 3D laminates and FCs with square arrays of fibers. Next, we investigate shear wave propagation along the fibers in these FCs deformed close to the instability point. Remarkably, analysis of shear wave polarizations can provide us with useful insights on the expected buckling shapes of the fibers. Thus, we find that fiber distribution in periodic FCs strongly influences buckling shapes of the fibers. 1. Key words: 3D change of material properties, Thermoelectric analysis, FGM link finite element, ANSYS.

Summary. *The contribution presents new electro-thermal link finite element for FEM analyses. This link element is suitable for modelling electro-thermal structures made of Functionally Graded Material (FGM) where 3D spatial variation of material properties is utilized. Moreover, thermoelectric effects, like Seebeck and Peltier effects are supported by the element. Semi-analytical method is used for derivation process of element matrices such electro-thermal link element. Spatial variation of material properties of the considered system is transformed to equivalent longitudinal-only variation of material properties using homogenization techniques based on volume fractions of individual material components. Because thermoelectric properties cannot be homogenized such way, these properties are directly set as longitudinal functional change in the link element. Representative numerical experiment of FGM electro-thermal structure where results from the new link element are compared with model prepared using standard finite elements in SW ANSYS are shown in the contribution. Accuracy and effectiveness of the link element is discussed and evaluated.*

1 INTRODUCTION

Nowadays, new materials are necessary for sophisticated structures like MEMS systems, advanced electronic devices, etc. Computer modelling of such complex systems, like structures with spatial variation of material properties (e.g. FGM) are, using commercial FEM code with classic elements, needs remarkable effort during preparation phase and sufficient computer equipment for solution phase because of necessity the numbers of elements and material models.

Finite elements for electric-thermal analyses of FGM materials considering Joule heat have been developed in [1]. This paper deals with derivation of new link finite element for two-way coupled static thermoelectric analyses considering Joule heat and also thermoelectric effects like Seebeck and Peltier effects. These effects describe direct conversion of thermal energy into electric energy (Seebeck effect) and conversion of electric energy into the temperature difference within the system (Peltier effect).

Let us consider straight link conductor, the conductor is a slender construction. Let the conductor is made of a mixture of two or more materials so its thermal, electric and thermoelectric material properties change according to chosen function. Under these conditions, we can consider one-dimensional system of differential equations and original method further explained in [2] for solving the differential equations for thermoelectric coupled analysis.

2 HOMOGENIZATION OF MATERIAL PROPERTIES

Let us consider a bar with circular cross-section according to Fig. 1. Its length is L [m] and diameter d [m] (cross section area A [m^2]). Let the FGM bar consists of two material components – matrix (denoted by index m) and fibre (index f) where fractions of individual constituents through the volume of the bar are functionally graded. We can consider matrix volume fraction $v_m(x,y,z)$ and fibre volume fraction $v_f(x,y,z)$ for every point (x,y,z) of the bar, so the change of material properties is 3D change. Moreover, let this change has polynomial character in every main direction $v_f(x,y,z) = \sum \varepsilon_u x^n y^m z^h$; $u = \max(r,s,l)$, $n = \{0;r\}$, $m = \{0;s\}$ and $h = \{0;l\}$ at which $v_m(x,y,z) = 1 - v_f(x,y,z)$, where grades of the polynomial changes r, s and l are for longitudinal and radial directions and through the individual circle's sectors of the bar, respectively (ε_u represents constant coefficients for individual coefficients of the polynomial). Fig. 1 also shows change of fibre volume fraction through the radial direction (d = 6.67 mm) and length (L = 200 mm) of the bar, where change through the circle's sectors of the bar is shown using parametric plot of surfaces (only 6 of total 12 surfaces – sectors – are shown). Thick lines in this Fig. 1 represent fibre volume fraction in chosen layers and sublayers (described in further sections of this contribution) of the bar that are necessary for calculation of homogenized material properties for electric and thermal fields.

The process of homogenization using division of the bar into layers (in radial direction) and sublayers (for chosen circle's sectors) according to extended mixture rule [3] and laminate theory [4] is shown in Fig. 2. The result of such homogenization process is equivalent homogenized material property (electric and thermal conductivity) with polynomial change only in longitudinal direction (through the other main directions of the bar the material property has constant value derived from longitudinal change). For steady-state electro-thermal analysis, the homogenization process need to be performed separately for final homogenized electric conductivity of the bar and for final homogenized thermal conductivity of the bar (both based on electric or thermal conductivities of fibre and matrix constituents of the FGM material, respectively).

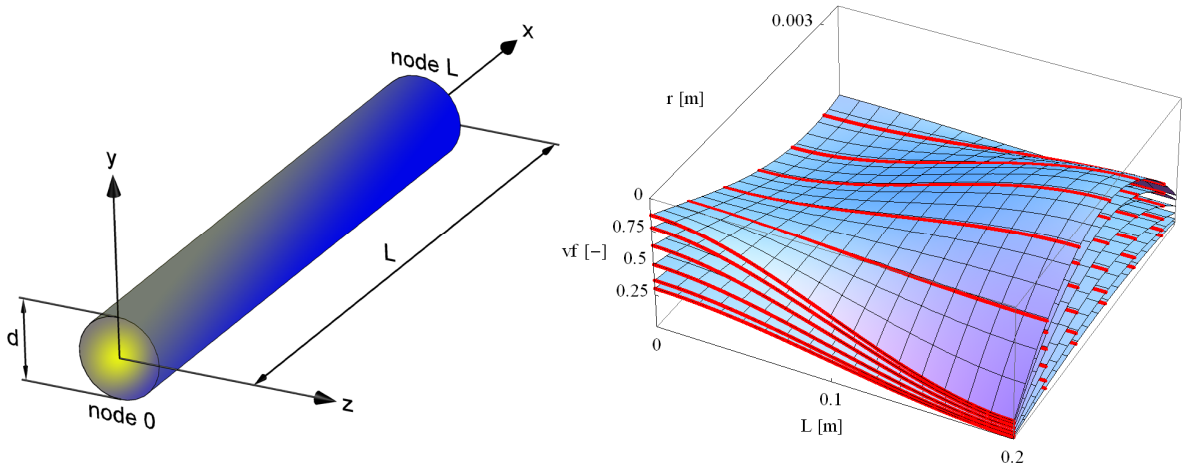

Fig. 1: FGM bar with spatial change of material properties (left), change of fibre volume fraction through the length, radial direction and circle's sections of the bar (right)

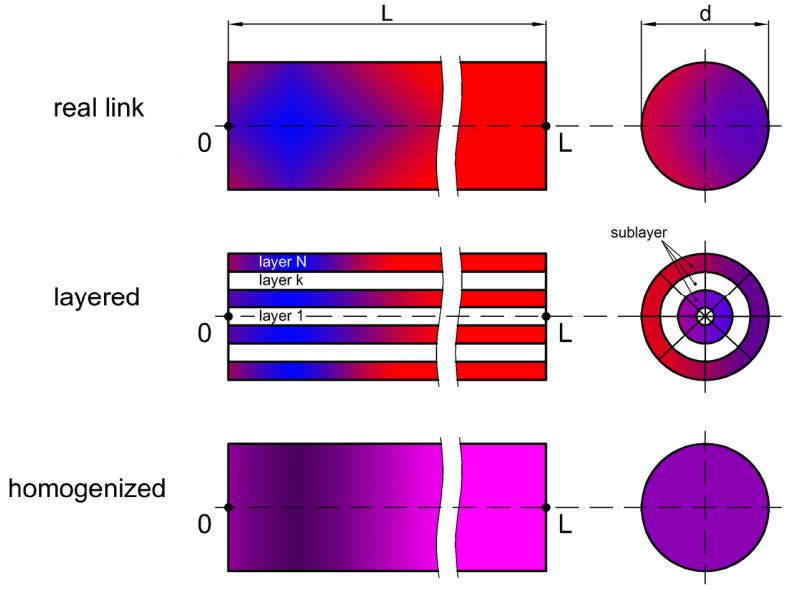

Fig. 2: Graphic representation of the homogenization process

For thermoelectric coupling that results in Seebeck and Peltier effects, Seebeck coefficient $\alpha(x, y)$ of the whole conductor needs to be known. This material property cannot be calculated according to the homogenization process based on extended mixture rule and laminate theory, because this material property is not given according to volume fractions of individual material components (expect the Joule heat, thermoelectric effects are significant especially for semiconductor materials and the behaviour of the semiconductors is given according to atomic structure, not according to volume fraction of individual admixtures). Moreover, the value of Seebeck coefficient can also be negative number. The determination of final Seebeck coefficient

according to material properties of individual components is beyond the scope of this article. For our model case the final Seebeck coefficient will be chosen directly as a polynomial function $\alpha(x)$ for longitudinal direction of the homogenized conductor.

3 MATHEMATICAL BACKGROUND FOR TWO-WAY COUPLED THERMOELECTRIC ANALYSIS

Thermoelectric and electric-thermal effects like Joule heat, Seebeck, Peltier and Thomson effects are described by set of two thermoelectric constitutive equations (static analysis) [5]:

$$\begin{aligned} \mathbf{q} &= [\![\Pi]\!] \cdot \mathbf{J} - [\![\lambda]\!] \cdot \nabla T \\ \mathbf{J} &= [\![\sigma]\!] \cdot (\mathbf{E} - [\![\alpha]\!] \cdot \nabla T) \end{aligned} \tag{1}$$

where $\mathbf{q}$ [Wm^{-2}] is heat flux vector, $\mathbf{J}$ [Am^{-2}] is electric current density vector, $[\![\Pi]\!]$ [V] is Peltier coefficient matrix, $[\![\lambda]\!]$ [Wm^{-1}K^{-1}] is thermal conductivity matrix, T [K] is absolute temperature, $\mathbf{E}$ [Vm^{-1}] is electric field intensity vector, $[\![\sigma]\!]$ [Sm^{-1}] is electric conductivity matrix and $[\![\alpha]\!]$ [VK^{-1}] is Seebeck coefficient matrix.

These constitutive equations are coupled by set of governing equations for static thermal and electric fields:

$$\begin{aligned} \nabla \cdot \mathbf{q} &= P \\ \nabla \cdot \mathbf{J} &= 0 \end{aligned} \tag{2}$$

where P [Wm^{-3}] is heat generation per volume unit.

In general, we can write for electric field intensity, Peltier coefficient and heat generation:

$$\begin{aligned} \mathbf{E} &= -\nabla\varphi & P &= P_J + P_{aux} \\ [\![\Pi]\!] &= T[\![\alpha]\!] & P_J &= [\![\sigma]\!]^{-1}\mathbf{J}^2 \end{aligned} \tag{3}$$

where φ [V] is electric potential, P_J [Wm^{-3}] is Joule heat per volume unit and P_{aux} [Wm^{-3}] is auxiliary heat generation per volume unit.

Applying (1) and (3) into (2) we can write for 1D system (longitudinal direction x):

$$\begin{aligned} \frac{d}{dx}[T(x)\alpha(x)J(x)] - \frac{d}{dx}\left[\lambda(x)\frac{dT(x)}{dx}\right] &= \frac{J^2(x)}{\sigma(x)} + P_{aux}(x) \\ \frac{d}{dx}\left[\sigma(x)\frac{d\varphi(x)}{dx}\right] + \frac{d}{dx}\left[\sigma(x)\alpha(x)\frac{dT(x)}{dx}\right] &= 0 \end{aligned} \tag{4}$$

4 FEM EQUATIONS FOR FGM LINK CONDUCTOR USING SEMI-ANALYTICAL METHOD FOR SOLUTION OF LINEAR DIFFERENTIAL EQUATIONS WITH VARIABLE COEFFICIENTS AND RIGHT-HAND SIDE

Procedure for solving differential equations with variable coefficients and right-hand side, which is presented in [2] is described in this chapter. General formula of such differential equation is:

$$\sum_{u=0}^{m} \eta_u(x) y^{(u)}(x) = \sum_{j=0}^{g} q_j a_j(x), \tag{5}$$

where:

m – order of the differential equation
$y(x)$ – unknown function of independent variable x
$y^{(u)}(x)$ – u^{th} derivative of the unknown function
$\eta_u(x)$ – polynomial variable coefficient for u^{th} derivative on the left-hand side of the differential equation
g – order of a polynomial on the right-hand side of the differential equation
q_j – constant coefficient for j^{th} power of the right-hand side polynomial
$a_j(x) = \frac{x^j}{j!}$ – auxiliary function for the right-hand side polynomial formulation

at which $x \in \langle 0; L \rangle$, where L is the length of considered interval of unknown solution.

The solution of the differential equation with variable coefficients has the form according to [2]:

$$y^{(u)}(x) = \sum_{i=0}^{m-1} y_0^{(i)} c_i{}^{(u)}(x) + \sum_{j=0}^{g} q_j b_{j+m}^{(u)}(x), \tag{6}$$

The solution of the differential equation (5) lies in determining the transfer functions generally labelled $c(x)$ and $b(x)$ that appear in the solution. First, the functions $b_{j+m}^{(u)}(x)$ are calculated using power series and recursive process, considering $u = \{0; m\}$ and $j = \{0; g\}$. It is necessary to guarantee the convergence of the series for a given interval $x \in \langle 0; L \rangle$ for successful calculation of these functions. This is always true only for constant coefficients η_u of the differential equation. It is often necessary to divide the interval of x into the shorter sections (in our case the independent variable is geometric variable, for example $x = L$ is the length of the bar) for variable coefficients $\eta_u(x)$, and thus determine the solution also for inner region of the bar (where $x \in (0; L)$). Calculation of the transfer functions and also automatic division of the interval for non-convergence behaviour of the series is included in a computer code and listed in [2].

The differential equations suitable for presented semi-analytical solution method must fulfil the following requirements:

– one independent variable of the function
– polynomial variable coefficients of the differential equation
– polynomial character of the right-hand side of the differential equation
– known interval of the independent variable where the solution of the differential equation needs to be determined

The order of the differential equation and the order of the right-hand side are arbitrary.

The described procedure of calculation such differential equations is suitable for calculation of electric and / or thermal field within the bar (1D task with only one independent variable), where change of material properties (electric and / or thermal conductivity and / or thermoelectric Seebeck coefficient) has polynomial (therefore variable) character.

Figure 3 shows geometry and physical quantities for thermoelectric analysis considering bar structure for which final FEM equations for such coupled analysis are presented.

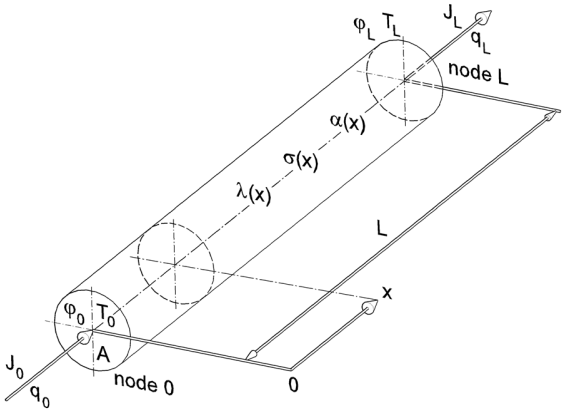

Fig. 3: Two-nodal conductor for thermoelectric analysis

Considering abovementioned semi-analytical method, the system of FEM equations for thermal field in the conductor can be expressed as:

$$\begin{bmatrix} c_0(L)+\dfrac{\alpha_0 J_0}{\lambda_0}c_1(L) & -1 \\ c_0(L)-\dfrac{c_1(L)c_0'(L)}{c_1'(L)} & \dfrac{c_1(L)\alpha_L J_L}{c_1'(L)\lambda_L}-1 \end{bmatrix}\begin{bmatrix} T_0 \\ T_L \end{bmatrix} = \begin{bmatrix} \dfrac{c_1(L)}{\lambda_0}q_0-\sum_{j=0}^{g}\varepsilon_j b_{j+2}(L) \\ \dfrac{c_1(L)}{c_1'(L)}\left(\dfrac{-q_L}{\lambda_L}+\sum_{j=0}^{g}\varepsilon_j b_{j+2}'(L)\right)-\sum_{j=0}^{g}\varepsilon_j b_{j+2}(L) \end{bmatrix} \tag{7}$$

The temperature within the range of the conductor is then:

$$T(x)=c_0(x)T_0+c_1(x)\frac{T_0\alpha_0 J_0-q_0}{\lambda_0}+\sum_{j=0}^{g}\varepsilon_j b_{j+2}(x) \tag{8}$$

FEM equations for electric field are:

$$\begin{bmatrix} -c_0(L) & 1 \\ -c_0(L) + \dfrac{c_1(L)c_0'(L)}{c_1'(L)} & 1 \end{bmatrix} \begin{bmatrix} \varphi_0 \\ \varphi_L \end{bmatrix} = \begin{bmatrix} -\dfrac{c_1(L)}{\sigma_0} J_0 - c_1(L)\alpha_0 T_0' + \sum_{j=0}^{g} \varepsilon_j b_{j+2}(L) \\ -\dfrac{c_1(L)}{c_1'(L)} \left(\dfrac{-J_L}{\sigma_L} + \alpha_L T_L' + \sum_{j=0}^{g} \varepsilon_j b_{j+2}'(L) \right) + \sum_{j=0}^{g} \varepsilon_j b_{j+2}(L) \end{bmatrix} \tag{9}$$

And the electric potential within the range of the conductor:

$$\varphi(x) = c_0(x)\varphi_0 - c_1(x)\left(\frac{J_0}{\sigma_0} + \alpha_0 T_0'\right) + \sum_{j=0}^{g} \varepsilon_j b_{j+2}(x) \tag{10}$$

FEM equations for two-way coupled thermoelectric analysis need to be solved using iterative algorithm. During iteration process it is necessary to find substitutional functions for results obtained from FEM equations (results of these FEM equations are not continuous functions but only sets of discrete values) and also it is necessary to convert non-polynomials into polynomials.

5 THERMOELECTRIC ANALYSIS OF FGM LINK CONDUCTOR - NUMERICAL EXPERIMENT

In this chapter there will be one academic example of thermoelectric analysis of given FGM link conductor presented. The task will be solved using our new approach, by commercial FEM code ANSYS and also by numerical solution of differential equations in software Mathematica due to comparison reasons.

Let us consider electric conductor with circular cross-section according to Fig. 1. Its length is $L = 200$ [mm] and diameter $d = 6.67$ [mm]. Let the conductor consists of mixture of two component materials – matrix (index m) with constant electric conductivity $\sigma_m(x, y) = 1.429 \times 10^6$ [Sm^{-1}] and thermal conductivity $\lambda_m(x, y) = 1.333$ [$\mathrm{Wm}^{-1}\mathrm{K}^{-1}$], and fibre (index f) with electric conductivity $\sigma_f(x, y) = 1.111 \times 10^7$ [Sm^{-1}] and thermal conductivity $\lambda_m(x, y) = 450$ [$\mathrm{Wm}^{-1}\mathrm{K}^{-1}$]. Volume fraction of individual components is functionally changed according to chosen polynomial, graphically shown in Fig. 1.

Using extended mixture rule for chosen number of layers ($N = 6$) and 12 sublayers – segmentation of the circular cross-section, we get longitudinal variation of effective electric and thermal conductivities for individual layers and using laminate theory we can calculate also homogenized electric and thermal conductivities of FGM conductor. The equations of homogenized electric and thermal conductivities are:

$$\sigma^H(x) = 3.912 \times 10^6 + 1.035 \times 10^8 x^2 - 3.451 \times 10^8 x^3 \ [\mathrm{Sm}^{-1}]$$
$$\lambda^H(x) = 116.401 + 4797.41 x^2 - 15\,991.4 x^3 \ [\mathrm{Wm}^{-1}\mathrm{K}^{-1}]$$

Let us consider final Seebeck coefficient for whole conductor according to chosen polynomial function (academic example, without considering homogenization process based on mixture of the components):

$$\alpha(x) = 2 \times 10^{-4} - 5 \times 10^{-3} x^2 \ [\mathrm{VK}^{-1}]$$

We assume static state for thermoelectric analysis. In nodes 0 and L there are electric potential, temperature, current density and heat flux specified, so the boundary conditions (see Fig. 4) are:

$$\varphi(0) = 0 \ [\mathrm{V}]; \qquad T(0) = 273 \ [\mathrm{K}]$$
$$J(L) = 1.121 \times 10^{6} \ [\mathrm{Am}^{-2}]; \qquad q(L) = 14\,154.2 \ [\mathrm{Wm}^{-2}]$$

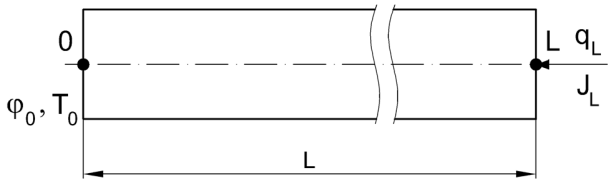

Fig. 4: Boundary conditions of the model

We also created 3D model in code ANSYS [6], we used 21 000 SOLID226 elements (20 node brick-elements). The task was also solved in software Mathematica [7], where the differential equations (5) with specified boundary conditions and homogenized material properties were numerically solved using iterative algorithm. Finally, the task was also solved by only one our new developed two-nodal link element using FEM equations (7) and (9) for nodal points of the link and with equations (8) and (10) for chosen points within the link. In Fig. 5 and Fig. 7 we can see calculated longitudinal distribution of the electric potential and temperature in the conductor, respectively. In Fig. 6 and Fig. 8 there are shown distributions of the electric current densities and heat fluxes for chosen layers (2nd, 4th and 6th layer) within the 2nd sublayer, respectively.

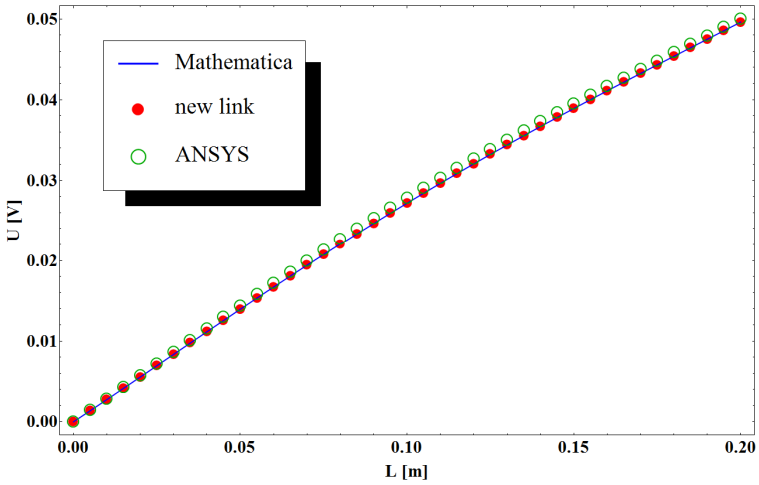

Fig. 5: Distribution of the electric potential through the length of the conductor

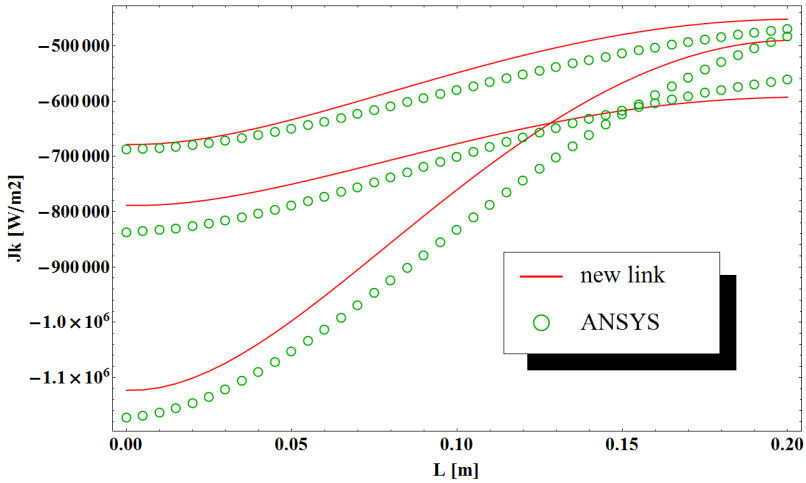

Fig. 6: Longitudinal distribution of the current densities in the chosen layers of one sublayer of the conductor

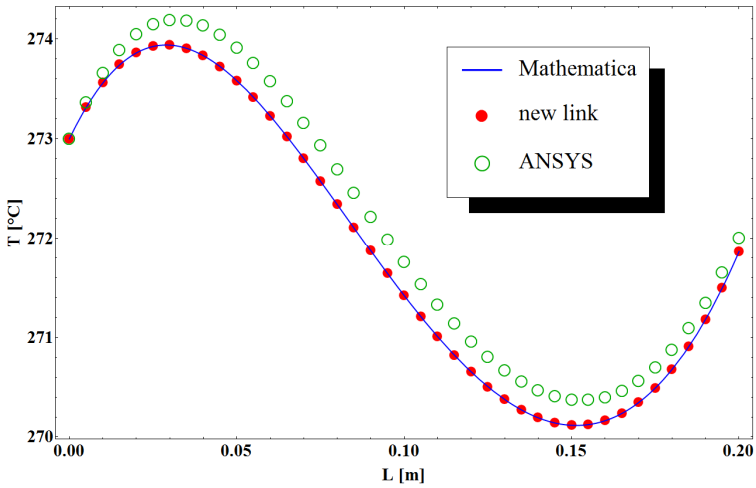

Fig. 7: Distribution of the temperature through the length of the conductor

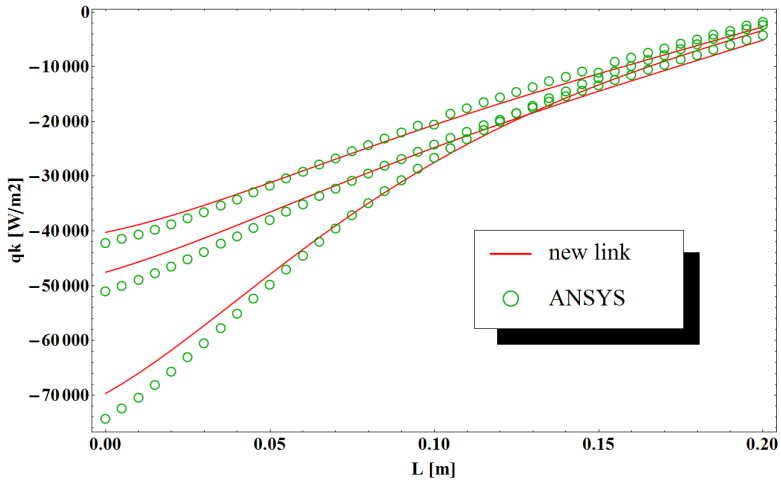

Fig. 8: Longitudinal distribution of the heat fluxes in the chosen layers of one sublayer of the conductor

In Fig. 7 it can be seen the cooled zone within one part of the model. This is due to Peltier effect based on different Seebeck coefficients applied in individual parts of the model and electric current passing through the conductor.

There is small difference in the results between ANSYS solution and calculation using the new approach because of substitutional functions used for conversion non-polynomials into polynomials during iterative process. Another differences in the results are due to fact that our approach is based on reduction of the real 3D system into 1D problem. But we can see from Fig. 5 – Fig. 8 that obtained results correspond to ANSYS 3D simulation very well.

6 CONCLUSIONS

New finite link element for two-way coupled static thermoelectric analyses for FGM with 3D spatial change of material properties has been developed in this contribution. New FEM equations with consideration Joule heat, and thermoelectric effects, like Seebeck and Peltier effects, were derived. Numerical example with good agreement between calculations with just only one new link element and commercial FEM code that uses numbers of classic elements have been presented. The new approach fully agrees with numerical solution for 1D differential equation of thermal and electric fields calculated using iterative algorithm. So, effectiveness and accuracy of the new developed link element for these analyses are at a high level.

Models and Software for Free Energy-Based Virtual Drug Screening

Emilio Gallicchio*

*Brooklyn College and Graduate Center of CUNY

ABSTRACT

We will describe recent progress on the development of a single-decoupling alchemical binding free energy model, its efficient implementation on graphical processing units (GPUs), and applications to large-scale virtual drug screening campaigns. The free energy of binding provides a complete description of the likelihood of association between molecules because it includes from first principles entropic and conformational reorganization effects which are neglected, or only empirically estimated, by simpler models. We will present illustrative cases in which, for example, compounds with favorable energetic interactions do not bind strongly the target receptor because to do so they incur intramolecular strain and entropic penalties. By screening out such cases, free energy models can lead to higher drug screening accuracy than currently achievable with docking and scoring protocols. However, due to perceived barriers to entry, complex setup and high computational requirements, free energy models of molecular binding are still not widely adopted in academic and industrial research. To address these challenges, we have developed a streamlined and automated single-decoupling version of the well-known double-decoupling method used in drug optimization and we have implemented it on massively parallel graphical processing units (GPUs). The single-decoupling method, together with parallel Hamiltonian hopping conformational sampling, speeds up by orders of magnitude the convergence of of binding free energy estimates. The GPU implementation as part of the OpenMM library is up to 100 times faster than optimized CPU implementations. We will present results of the deployment this computational framework protocol on GPU farms illustrating the advantages as well as the conceptual and technical challenges of the methodology. 1. Quasi-static Crack Propagation Problems in PD-FEM Coupled Models

Ugo Galvanetto*, Mirco Zaccariotto**, Tao Ni***

*University of Padova, Italy, **University of Padova, Italy, ***Hohai University?, China

ABSTRACT

Peridynamics (PD) is a family of non-local continuum theories proposed in a series of papers since the year 2000 [1], which, by adopting an integral formulation, does not make use of spatial derivatives. For that reason, PD based computational methods are successfully used to study problems with crack propagation, in particular they have been applied to the solution of dynamic crack propagation in brittle materials. However there are crack propagation problems in which the dynamic effects are negligible, such as those associated to fatigue phenomena. It is necessary to equip PD based computational tools with static solvers. The most popular approach adopted to solve non-linear problems is the Newton-Raphson algorithm which cannot be easily used in computational tools based on PD because most PD codes work on fragile fracture adopting the prototype microelastic brittle material (PMB) which assumes that the relation between bond stretch and bond force is linear up to a maximum stretch value, beyond which the bond force drops to zero (elasto-brittle material). The discontinuous definition of the PMB model prevents a straightforward application of standard Newton-Raphson algorithms. Therefore, its use in implicit static codes is problematic. This might be one of the reasons why static crack propagation phenomena are not commonly addressed when using PD-based numerical methods. We introduce a simple and accurate way to perform an implicit solution of static problems in which the usual PMB model is adopted: the sequentially linear approach [2]. Moreover we use it in conjunction with the FEM-PD coupling technique shown in [3]. In this manner we obtain a way to increase efficiency and flexibility of PD-based codes. The paper will demonstrate the potentialities of the proposed method by studying crack propagation phenomena in 2D systems. The effects of the presence of holes and initial cracks under static load conditions will be analysed. Results will be evaluated taking into account different horizon dimensions, grid sizes, initial crack lengths and crack orientations. References [1] S. A. Ultrafast Laser-excited Acoustic Vibrations of Single Gold Nanorods

Yong Gan*, Zheng Sun**, Yonggang Shen***

*Zhejiang University, **Zhejiang University, ***Zhejiang University

ABSTRACT

The acoustic vibrations of single gold nanorods are important for their applications in ultrasensitive sensing and nanooptics. Ultrafast laser irradiation has been a commonly used method to excite the vibrations of gold nanorods. The atomistic simulations for the vibrations of individual single-crystal and penta-twinned gold nanorods by femtosecond laser excitation have been performed [Gan et al., 2015a, 2015b, 2016], using a method that couples molecular dynamics (MD) with the two temperature model (TTM). The frequencies for the excited extensional and breathing modes of gold nanorods are obtained via the simulated nanorod responses, and then used to determine the elastic modulus of gold nanorods, in combination with continuum elasticity. With the decrease of nanorod width, the modulus of single-crystal gold nanorods decreases while the twinned nanorods become stiffer. It is shown that the elasticity theory based on the long-wavelength limit could fairly well describe the extensional periods of nanorods with an aspect ratio as small as ?2.4. The breathing mode of single-crystal nanorods characterized by the motion at the vertices is observed. For twinned nanorods, two breathing modes with the motions at the vertices and edges of the pentagonal cross-section are illustrated. It is demonstrated that the breathing periods of nanorods with an aspect ratio down to ?2.5 could be well predicted by the continuum elastic model in the limit of an infinitely long rod, with the use of bulk elastic constants. In addition, we find that the breathing vibrations of the penta-twinned nanorods are more affected by the crystal structure effect than those of single-crystal nanorods. Keywords: gold nanorods; acoustic vibration; mechanical properties; size effect; continuum elasticity. ABSTRACT

Recently, a new self-powered energy-harvesting sensor has been invented at the Michigan State University, [1, 2]. The mentioned sensor has floating gates, which can be set at some threshold voltages. When the voltage induced in the piezoelectric material of the sensor exceeds one of the specified thresholds the time counter is triggered. The symbolic dynamic analysis is used in order to find the effective thresholds for the maximum detectability of the change due to any damage based on Shannon entropy. For this, a baseline needs to be constructed using the undamaged plate case to set the thresholds based on the strain time history of the plate. Hence, some tests on a pristine plate subjected to a harmonic force has been conducted. Then, the time series on the strain event is sorted and discretized into equally populated subspaces by specifying relevant thresholds. Once the sensors have been set to these thresholds, the posterior state of the structure is monitored based on the accumulated time that each sensor exceeds its specified threshold. These accumulated times will show how much the system deviated from the initial condition. This can be done by finding the distance between the cumulative probability distribution function of the damaged plate and comparing it to the uniform distribution of the strain time history of the pristine condition. The outcomes demonstrate the capability of the method for monitoring damage propagation in similar structures. ABSTRACT

The production of metal parts via laser powder bed fusion (L-PBF) additive manufacturing is rapidly growing. However, in order for components produced via L-PBF to be used in critical applications, a high degree of confidence is required in their quality. An essential piece for such qualification is the ability to accurately know the stress state within a part. Since experimental measurement is often not feasible, having a validated model capable of reliably simulating these stresses would be extremely valuable. In this work, four Ti-6Al-4V arch-bridge shaped specimens were built via L-PBF using four different scan strategies: continuous scan aligned with the x-axis, continuous scan at 45 degrees to the x-axis, island scan aligned with the x-axis, and island scan at 45 degrees to the x-axis. A 90-degree rotation in scan orientation was performed after each layer for all four cases. The post-build residual stress in these components was determined by using x-ray diffraction to measure the strains present within the bridges, both while still attached to the base plate and after one leg had been cut off the base plate. Thermo-mechanical simulations of the bridge builds were performed using the parallelized multiphysics code Diablo. As the large range of time and length scales involved in the process prohibit simulation at the physical process scale, an agglomeration/lumping strategy was employed to estimate the residual stress in a reasonable time frame. The layer size was agglomerated such that many physical layers were lumped into one larger computational layer. Similarly, the beam size was computationally enlarged. A material model was used which captures the strain rate dependence of Ti-6Al-4V at elevated temperatures and allows for complete stress and plastic strain relaxation near melt. Parameter studies were performed to investigate different agglomeration approaches for both accuracy and computational expense. Results from the simulations exhibited good qualitative agreement with the measured strains in the bridges. However, the x-ray diffraction measurements actually showed increased strains present in the bridges built via the island scan strategies, particularly near the edges of the parts. This increase in strains for the island scan strategies was not captured in the simulations, which predicted similar residual stress profiles for all four parts. A discussion of potential reasons for both the experimental and computational findings will be presented.

ABSTRACT

Multiscale design has become a promising research topic in recent years since some pioneering works. In order to pursue the much higher structural performance within an acceptable computational cost, this current work proposes a new multiscale topology optimization method for integrated design of the macrostructure and multiple kinds of material cells by considering three basic design elements, namely the distribution of material cells as well as the topologies of both the macrostructure and material cells. Two stages are mainly involved, including the distribution optimization and the concurrent optimization. At the first stage, a classic SIMP-based method combined with a defined post-processing mechanism is formulated to enable a multi-piece layout of the element densities, which works as the distribution of multiple kinds of material cells over the macro design domain based on the positive correlation between the element densities and material effective properties. The macrostructure would be divided into some kinds of sub regions and each sub region is featured with a kind of material effective property. At the second stage, the topologies of the macrostructure and material cells are optimized synchronously by the parametric level set method under the distribution of material cells, where the numerical homogenization method is applied to evaluate material effective properties. Several examples in 2D and 3D are provided to display the effectiveness of the proposed multiscale design method. Results indicate that the structural performance of the optimized multiscale structure can be further enhanced within an acceptable computational cost.

Development of a Finite Element/ Discontinuous Galerkin/ Level Set Method for the Simulation of the Polymer Filling Process

Puyang Gao*, Jie Ouyang**, Wen Zhou***

*Northwestern Polytechnical University, XI'an, China, **Northwestern Polytechnical University, XI'an, China, ***Northwestern Polytechnical University, XI'an, China

ABSTRACT

The filling process in the injection molding always involves the polymer melt and air with different flow characteristics, large density/viscosity ratios and the transient free surface, which is treated as a challenging viscoelastic-Newtonian two phase flow problem especially on the irregular domains. In this study, the complex filling process for the irregular cavity is simulated via a combined finite element (FEM)/discontinuous Galerkin (DG)/level set method with application to the socket with five inserts, which has been rarely investigated. The rheological behavior of the viscoelastic fluid is predicted according to the eXtended Pom-Pom (XPP) constitutive model, which is suitable to describe the viscoelastic behavior of the branched polymer melt. The division and fusion of the evolving melt front in the filling stage is captured by the simple and efficient level set method. In the computational framework, we mainly need to solve the Navier-Stokes equations to get velocity field and pressure, deal with the XPP constitutive equation to update the stress values and handle the level set equation to renew the location and profile of the interface. The splitting scheme is first utilized to decouple the viscoelastic incompressible Navier-Stokes equations to get three sub-equations and makes it possible to choose the equal order interpolation function pair. And then DG is employed to deal with the non-linear hyperbolic equation and FEM is used to solve the Poisson and Helmholtz equations. In addition, the second order Runge Kutta Discontinuous Galerkin (RKDG) method is employed to handle the XPP constitutive equation and the level set equation due to their hyperbolic nature. This combined algorithm is convenient to directly cope with the irregular region of the cavity and there is no need of any stabilization terms. We first investigate the filling process of the rectangular cavity without and with a diamond insert, and compare with other numerical and experimental results to illustrate the validity of the coupled method. Moreover, as an application case, we consider the cavity of the socket with five inserts in China and analyze the influences of the inlet velocity and elasticity on the physical quantities such as stresses, stretch etc., and the simulation results could provide some numerical predictions for the polymer industry. To the best of our knowledge, this is the first attempt to simulate the polymer filling process in the irregular cavity with several inserts based on the XPP constitutive model via the combined finite element/discontinuous Galerkin/level set method.

An Efficient and Accurate Method for the Transient Heat Conduction in 2D Periodic Structures

Qiang Gao*, Haichao Cui**, Ying Feng***

*State Key Laboratory of Structural Analysis for Industrial Equipment, Department of Engineering Mechanics, Dalian University of Technology, **State Key Laboratory of Structural Analysis for Industrial Equipment, Department of Engineering Mechanics, Dalian University of Technology, ***State Key Laboratory of Structural Analysis for Industrial Equipment, Department of Engineering Mechanics, Dalian University of Technology

ABSTRACT

An efficient and accurate method is developed to solve the transient heat conduction problems in two-dimensional (2D) periodic structures. For a 2D periodic structure, according to the physical feature of the transient heat conduction, the periodic property of the structure, and the physical meaning of the matrix exponential, it is demonstrated that the matrix exponential for a reasonable time step is a sparse matrix containing many identical elements. Next, based on the superposition principle of linear systems and the algebraic structure of the matrix exponential, computation of the response of the original 2D periodic structure is transformed into computation of the responses of the small-scale models with several unit cells. Finally, the precise integration method (PIM) is used to compute the temperature responses of the small-scale models. The proposed method not only inherits the accuracy and stability of the PIM but also achieves significantly improved computational efficiency in terms of both computation time and storage requirements. A series of numerical examples demonstrate that the proposed method is more efficient than the Crank-Nicholson method and can obtain highly precise solutions even with a larger time step.

Topology and Shape Optimization Based Method for Miniaturization Design of Metallic Antenna

Renjing Gao*, Chuan Liu**, Qi Wang***, Shutian Liu****

*Dalian University of Technology, **Dalian University of Technology, ***Dalian University of Technology, ****Dalian University of Technology

ABSTRACT

To meet the stronger and stronger requirement of miniaturization and integration of the wireless communication system, the antennas are expected to be miniaturized correspondingly and should be carefully designed. As a rule, miniaturization of antenna can be achieved by designing the antenna operating at a lower frequency band. Among various design methods of miniaturized antenna proposed in the literature, topology optimization attracts intense interests due to its ability of flexibly distributing the metallic materials. But it is shown that the antenna performance is extremely sensitive to the grey elements remained in the topology optimization results. To overcome this kind of sensitive issue, this work presents a topology and shape optimization based method for metallic antenna's miniaturization design. The concept configuration of antenna is obtained through topology optimization firstly. The above sensitive issue is well illustrated through a typical example, and the mechanism of this sensitive issue is thoroughly analyzed and explained. Then a shape optimization scheme is built by describing the key boundary of the antenna with Bessel curves. By adjusting the location of points of the Bessel curves, the shape of the antenna can be flexibly optimized. A new configuration of miniaturized antenna is obtained with the proposed design method. The miniaturization index of the designed antenna is demonstrated better than any result obtained with dimension optimization. Compared to the original result obtained by topology optimization, both the return loss and the frequency bandwidth of the design are improved. In addition, the boundary of the design is more smooth to ensure the antenna can be easily fabricated. The proposed type of design method can also be extended to the optimization of other metallic devices.

ABSTRACT

According to the classical Eshelby inclusion problem, we introduce a new linear relation to calculate internal stresses in ?/? ? microstructures of superalloys via an effective stiffness method. To accomplish this, we identify regions with almost uniform deformation behavior within the microstructure. Assigning different eigenstrains to these regions results in a characteristic internal stress state. The linear relation between eigenstrains and internal stresses, as proposed by Eshelby for simpler geometries, is shown to be a valid approximation to the solution for complex microstructures. The Fast Fourier Transformation method is chosen as a very efficient numerical solver to determine the effective stiffness matrix. Numerical validation shows that this generalized method with the effective stiffness matrix is efficient to obtain appropriate internal stresses and that it can be easily used in the crystal plasticity finite element model to consider the influence of internal stresses on plasticity and creep kinetics in superalloys.

Multiscale Simulation on Mechanics of 2D Graphene Oxide Membranes

Wei Gao*

*University of Texas at San Antonio

ABSTRACT

Graphene oxide (GO) is an attractive building blocks in the design of advanced nanocomposite materials due to their reactive surface chemistry, which can enhance interfacial interactions while providing good in-plane mechanical properties. The mechanical properties of GO are of great importance for such applications. In this presentation, we present a multiscale simulation approach, including first principle based calculation, classical molecular dynamics simulation and continuum modeling, to study the deformation and failure of GO. Our findings demonstrate that GO should be treated as a versatile, tunable material that may be engineered by controlling chemical composition, rather than as a single, archetypical material.

Multiphysics Modeling on Fracture of Core-Shell Structured Si Nanoparticles During Charging/Discharging Cycling

Xiang Gao*, Chunhao Yuan**, Jun Xu***

*Beihang University, **Beihang University, ***Beihang University

ABSTRACT

Silicon is one kind of promising electrode materials for Lithium-ion batteries in the near future because of its high electrical capacity. But the mechanical fracture and electrical degradation due to large volume expansion/contraction of Si during lithiation/delithiation cycling have been the main barrier of its broad application. In order to reduce the impact of this volume change, many managements have been proposed in the Si electrode. Core-shell structure is a typical configuration in stress management of Si and some experimental and numerical studies have been carried out on this structure. Nonetheless, studies about the fracture of core-shell structured (CSS) Si nanoparticles when they are in touch with each other during charging/discharging process are still lacking. The Multiphysics coupling behavior of the CSS Si nanoparticle during electrochemical cycling were modeled in a finite element software and the mechanical fracture and corresponding electrical degradation were then analyzed. A core-shell-structured model that contained a Si nanoparticle wrapped with amorphous carbon was established. The system containing two contacting CSS Si nanoparticles were charged and discharged under constant voltages with different rate of charge. The volume change and associated stress simulated by the model were compared with the experiment data and matched well. The effects of the amorphous carbon with different thicknesses on the volume change, stress evolution and the corresponding mechanical fracture and electrical degradation of the particles were calculated. The present study showed a best combination of charge/discharge strategy and the thickness of wrapping layer and illustrate the failure behavior of different CSS configurations, which would give guidance for the Si based battery design and help to understand the macro failure mechanism of such a CCS particle.

A New Numerical Method -- Free Element Collocation Method (FECM)

Xiao-Wei Gao*, Hua-Yu Liu**, Lan-Fang Gao***

*Dalian University of Technology, **Dalian University of Technology, ***Dalian University of Technology

ABSTRACT

In this paper, a new numerical method, named as the Free Element Collocation Method (FECM), is proposed for solving general engineering problems governed by the second order partial differential equations (PDEs). The method belongs to the group of the collocation method, but the spatial partial derivatives of physical quantities are computed based on the isoparametric elements as used in FEM [1, 2]. The key point of the method is that the isoparametric elements used can be freely formed by the nodes around the collocation node. The analytical expressions for computing the global spatial partial derivatives of shape functions for the freely formed isoparametric elements are borrowed from the element differential method [3, 4]. To achieve a narrow bandwidth of the final system of equations, elements with a central node is recommended in the FECM. For this purpose a new 21-node quadratic element for 3D problems is constructed in this paper for the first time. Attributed to the use of the isoparametric elements which can guarantee the variation of physical variables consistent through all the elemental nodes, FECM can result in higher stable results than the traditional collocation method. In addition, the elements can be freely formed by local nodes, FECM has the advantage of mesh-free methods [5-7] to fit complicated geometries of engineering problems. A number of numerical examples of 2D and 3D thermal and mechanical problems are given to demonstrate the correctness and efficiency of the proposed method. Keywords: free element collocation method, element differential method, finite element method, mesh free method, thermal-mechanical problem.

Modeling the Ductile Damage Process in Commercially Pure Titanium

Xiaosheng Gao*, Jinyuan Zhai**, Tuo Luo***

*The University of Akron, **The University of Akron, ***The University of Akron

ABSTRACT

In this talk we present a constitutive model, which combines the models proposed by Stewart and Cazacu [1] and Zhou et al. [2], to describe the ductile damage process in a commercially pure titanium plate and to simulate its mechanical response. In particular, a Gurson-type porous material model is modified by coupling two damage parameters, accounting for the void damage and the shear damage respectively, into the yield function and the flow potential. The plastic anisotropy and tension-compression asymmetry exhibited by the commercially pure titanium plate are accounted for by a plasticity model based on the linear transformation of the stress deviator. The theoretical model is implemented in the general purpose finite element software ABAQUS via a user defined subroutine and calibrated using experimental data. Good comparisons are observed between model predictions and experimental results for a series of specimens in different orientations and experiencing a wide range of stress states. The model is shown to capture the effect of stress state and the change of fracture mechanism. The results also reveal the important effect of the plastic anisotropy and tension-compression asymmetry on the ductile damage process. An Overview of Hypercomplex Algebras for Sensitivity Analysis in the Finite Element Method

Manuel Garcia*, Mauricio Aristizabal**, Harry Millwater***, Daniel Ramirez****, Arturo Montoya*****

*U, **Universidad EAFIT, ***Uni, ****Univer, *****Univer

ABSTRACT

Complex taylor series expansion is a well known sensitivity computation method that lack subtraction cancellation error and has been successfully implemented for computation of first order single variable sensitivities in many fields including fracture mechanics, fluid mechanics and heat transfer. Dual numbers are a close relative of complex numbers and are step-size independent. Both methods have been extended to multiple imaginary directions, forming new algebras capable of computing high order sensitivities of multivariable functions. Multicomplex and Multidual (hyperdual) algebras have also been successfully used in engineering applications. All mentioned algebras belong to a broader set named Hypercomplex number system that contains other algebras such as doubles, quaternions, octonions, other Cayley-Dickson and Order Truncated Imaginary (OTI) algebras. This work shows that computation of sensitivities can be generally extended to any member of the Hypercomplex number system, where the algebra and method of implementation determines the influence of the step size in the derivative computation. Complex, MultiComplex, HyperDual, Quaternion, Octonion and OTI algebras were integrated into the finite element method, for applications in fracture mechanics and heat transfer problems. A performance comparison of the different methods was accomplished. It was observed that dual, multidual and OTI algebras are stepsize independent. Complex and multicomplex algebras show quadratic convergence and Cayley-Dickson algebras show linear convergence. However, the convergence iis dependent on the method of implementation. A common factor is that all algebras can be implemented so that results are free of subtraction cancellation error.

Understanding Fetal Cardiovascular Changes and the Role of Modelling

Patricia Garcia-Canadilla*, Bart Bijnens**

*DTIC, Universitat Pompeu Fabra, Barcelona, Spain, **DTIC, Universitat Pompeu Fabra, Barcelona, Spain. ICREA, Barcelona, Spain

ABSTRACT

Circulatory and haemodynamic remodeling occurs in many fetal conditions such as intrauterine growth restriction (IUGR), diabetic mothers, as well as in congenital heart disease (CHD) like aortic coarctation or univentricular hearts, and is likely to influence growth, organ development and postnatal outcome. Therefore, it would be very important and clinically relevant to better understand the mechanisms of cardiovascular remodeling in these fetal pathologies and how this reflects in cardiac structure and (clinically easily accessible) Doppler signals of the fetal circulation. This would allow us to find new biomarkers and therapeutic strategies and therefore improve future cardiovascular health of these fetuses. However, interpreting the fetal hemodynamic status in clinical practice is quite challenging, and some of the parameters, like blood pressures and organ resistances are not measurable. Computational models have proven to be a powerful tool to recreate and better understand hemodynamic changes, both under healthy and pathological conditions [1-5]. For example, model-based placenta resistance and compliance, assessed from 0D lumped models, were increased and brain resistance decreased in IUGR fetuses compared to normal ones, and adding these model-based parameters to the conventional Doppler parameters improve the detection of fetuses with adverse perinatal outcome. For more detailed modelling of the fetal cardiovascular systems, knowing the microstructure of the cardiac tissue is essential. For this, synchrotron-based phase-contrast X-ray imaging opens new perspectives. In conclusion, patient-specific computational models of the fetal circulation seem to be a good approach to assess hemodynamic and placental parameters than cannot be measured non-invasively in clinical practice, thus improving our understanding as well as the detection of fetuses with altered hemodynamics. Advances in the Simulation of Ship Navigation in Brash Ice

Julio García-Espinosa*, Borja Servan-Camas**, Jonathan Colom-Cobb***, Eugenio Oñate****

*International Center for Numerical Methods in Engineering, **International Center for Numerical Methods in Engineering, ***International Center for Numerical Methods in Engineering, ****International Center for Numerical Methods in Engineering

ABSTRACT

Abstract Brash ice is the accumulation of floating ice made up of blocks no larger than two meters across. Navigation in brash ice is becoming more usual as new navigation routes are being opened in the Artic regions. This navigation brings new concerns regarding the interaction of ice blocks with the ship. Developments are presented towards the simulation of this navigation condition including the interaction among the ship and the ice blocks. This work presents the advances in the development of a computational tool able to simulate this problem, based on the coupling of a Semi-Lagrangian Particle Finite Element Method (SL-PFEM) with a multi rigid-body dynamics tool. The Particle Finite Element Method [1] is a versatile framework for the analysis of fluid-structure interaction problems. The PFEM combines Lagrangian particle-based techniques with the advantage of the integral formulation of the Finite Element Method (FEM). It has been shown [1][2] to successfully simulate a wide variety of complex engineering problems, e.g. free-surface/multi-fluid flows with violent interface motions, multi-fluid mixing and buoyancy-driven segregation problems etc. The latest development within the framework of the PFEM is the X-IVAS (eXplicit Integration along the Velocity and Acceleration Streamlines) scheme [2][3]. It is a semi-implicit scheme built over a Semi-Lagrangian (SL) formulation of the PFEM. In this work, the SL-PFEM model has been coupled with a multibody dynamics solver, able to handle the interactions between thousands of bodies, representing the different ice blocks. The interaction between the fluid flow and the ice blocks is performed by enriching the finite element space at the boundaries of the different blocks. This work is part of the research project NICESHIP sponsored by the U.S. Office of Naval Research under Grant N62909-16-1-2236. A Chimera Method Based on Dirichlet-Dirichlet Coupling Applied to Moving Boundary Problems

Luciano Garelli*, Bruno Storti**, Mario Storti***, Jorge D'Elia****

*Centro de Investigación de Métodos Computacionales (CONICET-UNL), **Centro de Investigación de Métodos Computacionales (CONICET-UNL), ***Centro de Investigación de Métodos Computacionales (CONICET-UNL), ****Centro de Investigación de Métodos Computacionales (CONICET-UNL)

ABSTRACT

The main idea of the Chimera method is to generate independent and optimized meshes for the objects present in a computational domain and then using a coupling strategy, link all these objects in order to obtain the solution of the system. The method has appealing characteristics that are convenient for applications like simplified mesh generation, moving components or boundaries, local refinement, etc. In this work a Chimera method is presented and validated in the finite element context for structured and unstructured meshes by solving the system iteratively with BiCGStab (BiConjugate Gradient Stabilized method). A Dirichlet-Dirichlet coupling imposes the continuity of the unknown on overlapping sub domains and to transfer these values between the multiples domains, a third-order interpolation method is used in conjunction with a "pasting" penalization operator. Several numerical examples are shown in order to validate the solution and assessing the precision and computational cost of the method. Also, a convergence rate analysis is carried out for the proposed interpolation method. Finally, an advection-diffusion problem involving multiple moving boundaries is solved in order to show the potential of the presented scheme. The selected benchmark problems are well documented, both experimentally and numerically.

*Multi-scale Engineering Fluid Dynamics , Eindhoven University of Technology, Eindhoven, The Netherlands & Laboratori de Calcul Numèric , Universitat Politecnica de Catalunya, Barcelona, Spain, **Laboratori de Calcul Numèric , Universitat Politecnica de Catalunya, Barcelona, Spain, ***Multi-scale Engineering Fluid Dynamics , Eindhoven University of Technology, Eindhoven, The Netherlands, ****Laboratori de Calcul Numèric , Universitat Politecnica de Catalunya, Barcelona, Spain, *****Multi-scale Engineering Fluid Dynamics , Eindhoven University of Technology, Eindhoven, The Netherlands

ABSTRACT

Hydraulic fracturing is a challenging process to simulate, as it involves the coupling of various models: a solid model which describes the deformation of the rock induced by the fluid; a fluid flow model within the fracture, including a model for the representation of fluid leak-off to the rock formation; and a fracture propagation model. Besides, the input of the hydraulic fracturing model is affected by uncertainty. Many parameters involved in the process cannot be directly measured such as properties of the rock formations, whereas other process observables such as well pressures and seismic data can be obtained. In order to infer uncertain properties such as rock characteristics, an inversion problem has to be solved. Typically this means that one solves the forward problem many times. In this context, we make use of reduced order modeling to solve the forward problem at an affordable computational cost. More specifically, a Proper Generalized Decomposition (PGD), which provides an explicit parametric solution, is in our case used for a linear elastic solid model. In this contribution, we focus on the PGD formulation that efficiently deals with the solid problem in hydraulic fracturing, which parameterizes the stochastic material properties and geometric parameters. Furthermore, the way in which the explicit parametric solution is obtained and used to recover the solution of the forward problem is explained and considered in a hydraulic fracturing context.

Patterning and Morphogenesis of Seashells: Studies Based on the Coupling of Surface and Volume Growth with Nonlinear Elasticity

Krishna Garikipati*, Shiva Rudraraju**, Derek Moulton***, Alain Goriely****

*University of Michigan, **University of Wisconsin, ***University of Oxford, ****University of Oxford

ABSTRACT

ISeashells are an important model system for understanding mechano-morphological basis of the evolution of exoskeleton in invertebrates. Mantle tissue located at the growth front extracellularly secretes proteins and minerals and the calcification of these secretions leads to incremental growth of the exoskeleton. Most of the existing literature on the study of the complex forms (size, shape and ornamentations) in gastropods is descriptive. The mathematical understanding of the underlying mechano-morphology is at a nascent stage, primarily limited to reduced geometric representations or linear analysis of growth induced deformation modes of the mantle. In this work, we lay down the formulation for coupling of surface and volume growth that is essential to three-dimensional studies of the dynamics of seashell growth. We present a number of numerical studies of the evolving morphology driven by coupled surface and volume growth, which drive the form-defining nonlinear elastic deformation of the mantle. The focus is on understanding the effect of mantle geometry, growth rate and calcification rate on the resulting modes of deformation. Connections are made to a variety of antimarginal and commarginal ornamentations, including complex patterns such as hierarchical buckling and folding.

A Model to Predict the Progression of Abdominal Aortic Aneurysms over Time

T. Christian Gasser*, Christopher Miller**

*Department of Solid Mechanics, School of Engineering Sciences, KTH Royal Institute of Technology, Stockholm, Sweden. Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark, **Department of Solid Mechanics, School of Engineering Sciences, KTH Royal Institute of Technology, Stockholm, Sweden

ABSTRACT

Background. External (mechanical) stimuli influences cell function at the level of gene expression and thereby contributes to the overall control of vascular tissue structure and function. As with other biological tissues, vascular tissue seems to adapt towards stable homeostatic mechanical conditions, and failure of reaching homeostasis may result in pathologies. Computational biomechanical modelling presents as a critical tool towards the evaluation of the underlying mechanisms associated with tissue adaptation. Tissue adaptation has to obey basic physical principles, and even within these constraints, a large number of adaptation models have been proposed [1]. Such models are able to integrate the tissue's microstructure and directly address the differing length scales of individual tissue constituents, which in turn allows for the linking of biomechanical and biochemical adaptation aspects. Method. Here we consider a multi-scale microstructural constitutive description of vascular tissue that accounts for temporal tissue adaption, towards its impact upon the macroscopic stress state in patient-specific Abdominal Aortic Aneurysm (AAA) geometries [2]. The present work builds upon the aforementioned model through a series of further constitutive refinements. The formulations have been implemented at the Gauss point-level of a mixed finite element formulation (FEAP, University of California at Berkeley) and test cases reflect patient-specific AAA geometries that were reconstructed from Computed-Tomography Angiography images (A4clinics Research Edition, VASCOPS GmbH). Mass turnover of vessel wall constituents is described by rate equations, which directly control the time step of the non-linear FE calculations. Results and Discussion. The outlined approach allows for the effective solution of the non-linear numerical problem and as such, the simulation of patient-specific AAA progression. Our results show good correlation with clinical follow-up data [3]. However, due to the scarcity of relevant experiment data, key modeling steps are based on ad hoc assumptions. Consequently, much more interdisciplinary experimental work is required to validate our modeling activities. [1] T.C. Gasser, A. Grytsan. An HP-Hierarchical Framework for the Finite Element Exterior Calculus with Applications to Elasticity Problems

Robert Lee Gates*, Maximilian Rüdiger Bittens**, Udo Nackenhorst***

*Leibniz Universität Hannover, **Leibniz Universität Hannover, ***Leibniz Universität Hannover

ABSTRACT

The finite element exterior calculus (FEEC) [1] is a general framework for constructing and analyzing stable mixed finite element formulations, such as the locking-free discretization of the elasticity equations. The present work introduces a dimension-independent hp-hierarchical construction of the FEEC basis on the simplex together with a suitable simplicial mesh-structure, allowing for inhomogeneous p-adaptivity and local h-refinement. The h-hierarchy of the basis and the mesh-structure are closely linked, owing to the duality between the Whitney forms and simplicial cochains. By appropriately modifying the refinement equation [2], for the discrete approximation of differential 0-forms (Lagrange elements), the proposed construction yields the well-known hierarchical Schauder basis [3], while for differential forms of higher degree, an extended form of the Haar-wavelet basis is obtained. For certain problems, the lowest-order coefficients of the proposed bases can be interpreted as an a posteriori error indicator, guiding adaptivity. We apply the developed hp-adaptive framework to various mixed problems. As the canonical choice for verifying the method, we compute adaptive solutions to the different weak formulations of the Hodge Laplacian, elaborating on cases where traditional Lagrange finite elements would fail to provide the correct solution. Furthermore, we verify the numerical reproduction of the de Rham theorem by computing the cohomology classes of selected topologies. Finally, we compute benchmark problems from the field of solid mechanics in the incompressible limit. [1] D.N. Arnold, R.S. Falk, and R. Winther. Investigation of Plastic Deformation at Micro- and Nano-scale: Modelling and Comparison with Experimental Results

Riccardo Gatti*

*LEM, UMR 104 CNRS-ONERA

ABSTRACT

Modelling plastic deformation at the micro and nanoscale is a puzzling problem in material science. The presence of free surfaces and interfaces reduce the mean free path of dislocations and change the mechanical properties of materials. This change of properties cannot be taken into account neither in continuum plasticity models, because the discrete nature of plastic deformation cannot be neglected, nor in atomistic simulations, because the simulated volume is too small and the accessible time scale is limited. A reliable tool to model crystal plasticity at such scales is the Discrete-Continuum Model (DCM). The DCM is based on a coupling between 3D Dislocation Dynamics (DD) simulations and Finite Element (FE) method. The DD simulation code is in charge of the dislocation microstructure evolution, handling the discrete nature of dislocations, while displacement field and boundary conditions are handled by the FE simulation code. In particular, in the DCM framework, not only the interaction of dislocations with free surfaces and interfaces is recovered, but also plastic incompatibilities are naturally taken into account and complex loading, close to the experimental conditions, can be imposed to the simulated object. Here, the main features of the DCM are briefly presented, emphasizing the capability of studying the plastic deformation in nano-object using anisotropic elasticity. Then the mechanical behavior of single- and bi-crystalline Ni micro-samples is investigated, comparing the result of DCM simulations with experimental data. Finally, the intriguing possibility of computing X-ray diffraction maps, post processing simulation outputs, is highlighted.

ABSTRACT

The analysis and prediction of the degradation process and cracking of concrete struc-tures with numerical models is an important issue in the field of civil engineering. In order to describe the global behavior of a structure composed of quasi-brittle material as well as local fields, a continuous approach using nonlinear constitutive law (e.g. dam-age, plasticity,…) remains the most efficient one regarding the computational time. How-ever, one has to consider additional tools to extract discrete information about cracks like spacing and openings from these computations. The objective of this research is to pro-pose tools capable of extracting local information such as cracking using two post-treatment methods of a global finite element ana¬lysis. First, in the proposed method, a global non-linear finite element analysis of the whole structure is performed. This analysis reveals the zones of degradation that are to be reana-lyzed via a local analysis using two post-treatment methods. The first method combines a topological search method used to locate cracks developed by Bottoni et al. [1] and a continuous/discontinuous approach used to compute the crack opening initially proposed by Dufour et al. [2].. It consists in comparing the computed strain fields, with the analytical one derived from the displacement profile described as a strong discontinuity. Both strain fields are regularized using a Gaussian function. The crack opening can then be adjusted so as to reduce the gap between the regularized strain field and the regularized strong discontinuity strain field. Furthermore, a general formu-lation of these tools for 2D and 3D problem is proposed in this work. The direction of the mode I crack at a point is determined as the one which maximizes the crack opening along the associated 1D profile. The second method is a non-intrusive reanalysis at the local scale performed with a discrete model in order to extract fine information about crack opening. A region of in-terest (ROI) corresponding to the damaged area obtained from the global analysis is de-fined. Then, the loading steps corresponding to the steps of reanalysis are determined, where boundary conditions are extracted from the continuous displacement field and ap-plied on the non-free surfaces of the ROI. The material is described with a discrete ele-ment approach based on an assembly of polyhedral particles linked by Euler–Bernoulli beams with brittle behaviour. Further details concerning the discrete model used at the local scale can be found in [3]. The displacement fields obtained from the FE analysis are compared to the experimental data provided from the post-processing of the actual test in order to analyze the concord-ance of the results on the global scale. ABSTRACT

A new dynamical core suitable for numerical weather prediction over a wide range of length scales is under development at Environment and Climate Change Canada. As it is well-known, the stiffness due to the presence of rapidly propagating waves in the atmosphere renders traditional explicit methods impractical. The aim of our research is to explore an emerging class of exponential integration methods. These schemes have seen limited use in geophysical fluid dynamics due to efficiency issues. In order to circumvent some of these limitations, we recently introduced a new algorithm KIOPS for computing linear combinations of phi-functions that appear in exponential integrators. Theoretical analysis of the method and numerical simulations in a number of experimental frameworks demonstrates that KIOPS outperforms the current state-of-the-art adaptive Krylov algorithm PHIPM.

Large-scale Real-space Electronic Structure Calculations

Vikram Gavini*, Phani Motamarri**, Bikash Kanungo***

*University of Michigan, **University of Michigan, ***University of Michigan

ABSTRACT

Defects play a crucial role in influencing the macroscopic properties of solids—examples include the role of dislocations in plastic deformation, dopants in semiconductor properties, and domain walls in ferroelectric properties. These defects are present in very small concentrations (few parts per million), yet, produce a significant macroscopic effect on the materials behavior through the long-ranged elastic and electrostatic fields they generate. The strength and nature of these fields, as well as other critical aspects of the defect-core are all determined by the electronic structure of the material at the quantum-mechanical length-scale. Hence, there is a wide range of interacting length-scales, from electronic structure to continuum, that need to be resolved to accurately describe defects in materials and their influence on the macroscopic properties of materials. This has remained a significant challenge in multi-scale modeling, and a solution to this problem holds the key for predictive modeling of complex materials systems. In this talk, we present some key methodological developments that have enabled large-scale electronic structure calculations—as large as explicitly treating 10,000 atom Kohn-Sham density functional theory (DFT) calculations—taking us closer to addressing this significant challenge. In particular, the development of a real-space formulation for Kohn-Sham DFT and a finite-element discretization of this formulation [1,2], which can handle arbitrary boundary conditions and is amenable to adaptive coarse-graining, will be presented. The accuracy afforded by using higher-order and enriched finite-element discretizations, and the efficiency and scalability of the Chebyshev filtering algorithm in pseudopotential and all-electron Kohn-Sham DFT calculations will be demonstrated. Further, the development of a subquadratic-scaling approach (in the number of electrons) based on a subspace projection and Fermi-operator expansion will be discussed [3,4], which will be the basis for the future development of coarse-graining techniques for Kohn-Sham DFT that can enable accurate electronic structure calculations at macroscopic scales. GPU-based Topology Optimization for Thermoelastic Problems

Stefan Gavranovic*, Dirk Hartmann**, Utz Wever***

*Technical University of Munich, **Siemens AG, ***Siemens AG

ABSTRACT

Additive Manufacturing is not only revolutionizing manufacturing but also the way engineers create new designs. It provides opportunities to explore much larger design spaces. This opens the possibility to reduce design weight and increase its performance to so far unreachable levels. Topology Optimization [1] as a tool helps to obtain such optimal designs, however, today it is mostly limited to CAE users. Making corresponding design tools accessible to non-expert CAE users is a key for creativity and to efficiently exploit the opportunities promised by Additive Manufacturing [2]. Key to this challenge are interactivity and enhanced user experience. In order to enable nearly interactive Topology Optimization in 3D, we implemented an efficient geometric multi-grid method [3] on structured hexahedral meshes utilizing GPU computing capabilities for performing linear structural analyses. To circumvent boundary treatment issues which arise when using non-confomal hexahedral meshes we use a cut-cell approach alongside with augmenting weak formulation of equations by means of Nitsche method. In this way, we are able to achieve desired numerical accuracy of FEM solver which is an essential building block and the most time consuming part of the Topology Optimization process. Additionally, inspired by the nature of Additive Manufacturing process, we consider influence of thermal loads in the optimization process. User experience is enhanced by integrating our tool within CAD system, thus simplifying pre-processing stage for a simulation and ultimately making the topology optimization tool accessible to non-experts. The concept has been made available to a selected user base validating the approach. References: [1] Bendsoe, Martin Philip, and Ole Sigmund. Topology optimization: theory, methods, and applications. Comparison between Master-Master and Master-Slave Contact Formulations

Alfredo Gay Neto*, Peter Wriggers**, Debora Higa***

*University of São Paulo, **Leibniz Universität-Hannover, ***University of São Paulo

ABSTRACT

Computational contact models considering pointwise interactions are very useful. On this context, the master-slave contact formulation is known for its versatility in a finite element model. The election of nodes as slave points in a surface mesh together with the other surface parameterization (master) is the basis of the method. Then, slave points' movement are tracked along master surface. This constitutes the kinematic basis for the contact mechanical constraint enforcement, which is done in a pointwise manner. On the other hand, the master-master approach to account for contact [1] does not need the prior election of slave points. Both surfaces are treated as masters. They are re-parameterized along the model evolution. At each configuration, a pointwise interaction is searched. During the model evolution, the material points where contact takes place in both surfaces may change significantly. The advantage is to capture all such changes within a single contact pair search. Typically, one may find examples of this nature on rolling contact of non-conformal geometric profiles. In this context, the present work presents a comparative approach of master-slave and master-master contact formulations. The methods are compared with respect to both versatility and mathematical basis. Pros/cons of each technique are emphasized. We show that, mathematically, master-slave is a particular case of master-master contact formulation, coming from degeneration of two convective coordinates on a given surface, chosen a priori to be a slave point. A particular discussion is given to cases where overall contact may be well represented by a single pointwise interaction. Particularly, the enhanced master-slave presented in [2] is shown as a mid-step between master-slave and master-master, for the particular case on which each slave point is upgraded to a spherical surface. This shows to be useful in some applications involving spherical particles in contact with surfaces. Numerical examples will be given to support discussions. Particularly, beam-to-beam contact is taken as base-problem. [1] GAY NETO, A.; PIMENTA, P. M.; WRIGGERS, P. A Master-surface to Master-surface Formulation for Beam to Beam Contact. ABSTRACT

We consider several one-dimensional impact problems involving finite or semi-infinite, linear elastic flyers that collide with and adhere to a finite stationary linear viscoelastic target backed by a semi-infinite linear elastic half-space [1]. The impact generates a shock wave in the target which undergoes multiple reflections from the target boundaries. Laplace transforms with respect to time, together with impact boundary conditions derived in our previous work [2], are used to derive explicit closed-form solutions for the stress and particle velocity in the Laplace transform domain at any point in the target. For several stress relaxation functions of the Wiechert (Prony series) type, a modified Dubner-Abate-Crump (DAC) algorithm [3] is used to numerically invert those solutions to the time domain. These solutions compare well with numerical solutions obtained using both a finite-difference method and the commercial finite element code, COMSOL Multiphysics. The Final Value Theorem is used to show that the asymptotic (long observation time) stress and particle velocity is independent of target properties in linearly viscoelastic media with non-zero long-term equilibrium moduli, but depend only on the elastic properties of the flyer and half-space backing material. Alternatively, viscoelastic targets in which the long-term equilibrium modulus is zero, also exhibit both target length and viscosity dependent asymptotic stress; the asymptotic particle velocity is also position dependent in such targets. These results are useful for verification of viscoelastic impact simulations taken to long observation times. A Methodology for In Silico EVAR of Abdominal Aortic Aneurysms

Michael Gee*, André Hemmler**

*TU Munich, **TU Munich

ABSTRACT

Endovascular aneurysm repair (EVAR) is a widely used and well established technique to intervene before rupture of abdominal aortic aneurysms (AAA) occurs. However, EVAR can involve some unfavorable complications such as endoleaks or stent-graft (SG) migration. Such complications, resulting from the complex mechanical interaction of vascular tissue, SG and blood flow or incompatibility of SG design and AAA geometry, are difficult to predict. Finite element simulations can be a predictive tool for the selection, sizing and placement process of SGs depending on the patient-specific AAA geometry and hence reduce the risk of potential complications after EVAR [1]. In this contribution, we present a new virtual SG deployment methodology [5] to reproduce the final state of the deployed SG after intervention. We aim to find the final SG position in a patient-specific AAA geometry and evaluate the mechanical state of AAA and SG, such as contact forces or wall stresses. Three different constituents of the aneurysmatic tissue are considered: diseased aneurysmatic wall, intraluminal thrombus and calcifications [4]. Furthermore, the anisotropic mechanical behavior [2] of the aortic wall in the proximal and distal fixation zones of the SG are taken into account. The simulation process consists of two main steps. In a first step the SG is crimped, bent and moved by a tailor-made morphing algorithm to position the SG inside the AAA. Afterwards, the SG is released inside the AAA where it unfolds and makes contact with the luminal surface of the patient-specific vascular model. We consider mortar based frictional contact [3] between a sophisticated, finite deformation AAA and a SG composed of a parameterized, product specific (Cook Zenith Flex®) graft shell and stent wire frame that can undergo finite deformations. The simulation results of three patient-specific cases are compared to the geometry of the deployed SG taken from postinterventional CT scans. [1] F. Auricchio, M. Conti, S. Marconi, A. Reali, J. L. A New Phase-Field Formulation for Cohesive Fracture

Rudy Geelen*, Yingjie Liu**, John Dolbow***, Michael Tupek****

*Duke University, **Duke University, ***Duke University, ****Sandia National Laboratories

ABSTRACT

Recently, phase-field models have been proposed to regularize sharp crack fronts. These fracture models have gained popularity in no small part due to their ability to handle complex failure topologies, such as crack branching and coalescence, even in three-dimensional settings. In the phase-field community, the emphasis has been on a Griffith description of brittle fracture. However, most engineering materials are not perfectly brittle in the Griffith sense, but display ductility after reaching a critical strength. Often, there exists a fracture process zone ahead of the crack tip in which micro-crack and void initiation, growth and coalescence, as well as small-scale yielding, take place. If this zone is relatively large compared to the structural dimensions, one has to rely on cohesive fracture mechanics based strategies such as the cohesive zone approach. In this work, an attempt was made to outline a framework for dealing with cohesive fracture in a phase-field setting. The development of a phase-field model for cohesive fracture is a non-trivial extension of the model available for brittle fracture. Miehe and coworkers [1] were among the first to postulate a phase-field formulation with a threshold that exhibits a linear elastic response prior to strain softening. We build on this effort by deriving a free-energy functional that is consistent with the kinetics of cohesive fracture. The governing equations are formulated in terms of a macro and micro-force balance. The latter naturally handles the irreversibility of crack growth by means of a viscous regularization. The model employs a stress-based criterion as the crack driving force, in contrast to the conventional strain-based approach [2]. In addition, the use of a novel strain energy density function is proposed, allowing for the extension to fracture in anisotropic media. The resulting free-energy expression shares some similarities with earlier work in the field of gradient-damage modeling, in particular that of Lorentz et al. [3] The proposed approach is distinctly attractive as the regularization length is shown to have virtually no effect on the constitutive response, merely acting as a numerical parameter controlling the regularization of the fracture surface. Several benchmark problems are presented to demonstrate the features of the proposed phase-field model. A simple linear actuator model and its application to optimization of adaptive structures

Florian Geiger*, Jan Gade**, Malte von Scheven***, Manfred Bischoff****

*Institute for Structural Mechanics, University of Stuttgart, **Institute for Structural Mechanics, University of Stuttgart, ***Institute for Structural Mechanics, University of Stuttgart, ****Institute for Structural Mechanics, University of Stuttgart

ABSTRACT

In simulation of adaptive structures, often a model of the passive structure is created using commercial finite element software and the system matrices are then exported for further manipulation. Actuation and adaptivity are considered afterwards by introducing additional load cases or boundary conditions. Including effects like nonlinear behaviour of the structural response or system changes then causes great effort. We present a simple finite element for linear actuators that is derived with a constrained variational principle and includes the effect of actuation. The element offers the possibility to assemble the system matrices of the adaptive system directly in order to save effort when the structure is changed or nonlinear effects are included. Another important aspect is the additional insight into the structural behaviour of adaptive structures that can be won. Examples of simple truss structures using the presented element are conducted to exhibit potentials of adaptivity. The differences between including adaptivity before structural optimization and including adaptivity in the optimized passive structure are shown.

A Discontinuous Galerkin Immersed Boundary Solver for Compressible Flows: Efficient Time Integration for Artificial Viscosity Based Shock-Capturing

Markus Geisenhofer*, Björn Müller**, Florian Kummer***

ABSTRACT

In this talk, we study unsteady high Mach number flows in the context of the Euler and Navier-Stokes equations. We use a Discontinuous Galerkin (DG) solver [1] that was extended to immersed boundaries where the considered geometry is represented by the zero iso-contour of a level set function. We apply cell-agglomeration that averts problems with small and ill-shaped cut cells. In order to obtain a stable and accurate solution, discontinuous flow phenomena such as shocks have to be resolved properly. Particularly, we use a shock-capturing approach based on artificial viscosity. Recently, we coupled both approaches in order to reuse the geometrical flexibility of immersed boundaries. For shock-capturing, we follow the two-step strategy presented in [2]. First, a shock sensor that is based on the modal decay of the DG coefficients detects troubled cells. Second, artificial viscosity is applied to these cells in order to smooth the solution. To advance the solution in time, we use an explicit time integration scheme. In the aforementioned setting, a severe time step restriction is caused by the additional diffusive term that leads to a drastic reduction of computational efficiency. We tackle this problem by using a local time stepping (LTS) approach [3] that partitions the grid into cell clusters. These cell clusters are updated continuously according to their local time step restriction, which is beneficial for transient simulation runs. Meeting all these challenges, we present current results of a new efficient DG immersed boundary solver for compressible flows by combining a shock-capturing scheme with an adaptive LTS method. Moreover, we show first results of the successful combination with a dynamic load balancing strategy that enables a performant parallelization based on the LTS cell clusters. 3D Image Based Inspection and Finite Element (FE) Simulation of Additive Manufactured (AM) Parts

Kerim Genc*, Nicholas Brinkhoff**, Timothy Williams***, Tim Pawlak****, Lin Cheng*****, Albert To******, Steve Pilz*******, Ronald Gull********, Philippe Young*********

ABSTRACT

Additive Manufacturing (AM) of metal parts is becoming more common as an alternative approach to traditional methods because it has many benefits, not the least of which is the tremendous design freedom that it affords designers. However, the uncertainties of AM parts in terms of accuracy, quality, strength and reliability are still relatively high and therefor troubling to manufactures of critical components or systems. Simulation techniques are now being incorporated into the design process to help improve the quality of the AM design process, reduce weight and ensure a high probability of successful builds. Despite these efforts, however, there is still uncertainty in the differences between as-designed versus as-built AM parts, which leads manufacturers to ask the following question: “What are the differences between my design and the part that is actually manufactured and how will these differences affect performance in reality?” Companies are already spending a significant amount on 3D imaging technology like industrial Computed Tomography (CT) scanners for inspection, non-destructive evaluation and reverse engineering of Additive Manufactured (AM) parts. From CT scans, users can typically quantify porosity, crack/defect size, deviations from design etc. However, information, in and of itself, do not provide an understanding of how these defects and deviations from the desired design will affect performance in the real world. We will describe how the three domains of CT-imaging, AM and FE simulation are just now starting to connect because of a need to better understand the performance of the real as-manufactured part, not just a CAD design ideal. Typically, due to the knowledge gap between these domains, the adoption of this workflow from the 3D scan to a realistic FE simulation can be tortuous with engineers and technicians using a mix of open source, in-house and/or commercial tools to create an inefficient, unrepeatable workflow that can be an expensive drain on internal time and resources. We will demonstrate a proof of concept workflow where a lightweight bracket is designed/optimized to reduce weight and then built using the laser powder bed AM in a titanium alloy (Ti6Al4V). This bracket is then scanned via CT and then image based tools are used to inspect the geometry and generate an FE mesh, which is exported for simulation of the as built part. This workflow allows users to close the design loop and truly understand how defects and deviations in the manufactured part can affect performance in the real world.

Multilevel and Multifidelity Approaches for Uncertainty Quantification

Gianluca Geraci*, Alex Gorodetsky**, Michael Eldred***, John Jakeman****

*Sandia National Laboratories, **University of Michigan, ***Sandia National Laboratories, ****Sandia National Laboratories

ABSTRACT

Uncertainty Quantification (UQ) plays a fundamental role in the design and analysis of complex and realistic engineering systems that rely heavily on numerical simulations. While advancements have improved the efficiency of UQ algorithms in the last two decades, UQ remains challenging in the presence of high-fidelity numerical models. State of the art UQ algorithms require multiple evaluations of a complex computer code and the number of required simulations generally increases rapidly with the number of random parameters. As a result, performing UQ for high-fidelity models is hampered by the high computational cost of each realization. Multilevel and multifidelity algorithms have recently been introduced to overcome this limitation [1,2]. Their main idea is to gather realizations of different fidelities and/or discretization levels in order to accelerate the convergence of high-fidelity model statistics, and their key strategy is to achieve a variance reduction for the statistical estimator. In this talk we cover two main aspects of these techniques. First, we discuss relation between multilevel and control variate algorithms with respect to the properties of the system under analysis. Next, we compare and interpret both multilevel and control variate approaches within a new Bayesian multifidelity model management approach [3]. Numerical results for several test cases are presented and discussed to highlight the relevant features of the different approaches. [1] M.B. Giles. 'Multilevel Monte Carlo methods'. Benchmark Calculations of Shear-banding Polymer Solutions

Natalie Germann*, Soroush Hooshyar**

*Technical University of Munich, **Technical University of Munich

ABSTRACT

Many soft materials such as polymer solutions develop banded velocity and concentration profiles if the shearing deformation is large enough. Concentration gradients formed during processing can have a great impact on the final texture of a product. Using the generalized bracket approach of nonequilibrium thermodynamics, we developed a new two-fluid model for semi-dilute entangled polymer solutions to study the phenomenon of shear banding [1]. We included the Giesekus relaxation to account for the overshoot of the shear stress during the start-up of a simple shear flow. In addition, we included a second nonlinear relaxation term to capture the upturn of the flow curve at high shear rates. This term is similar to the term used in the Rolie-Poly model that accounts for convective constraint release and chain stretch, with the exception ob being now thermodynamically consistent. Finally, a new nonlocal stress-diffusion term was added to the time evolution equation of the polymer conformation to have smooth and unique profiles. The behavior of the new model was analyzed in three different benchmark geometries [1-2]. For the circular Couette and pressure-driven channel flow problems, we employed a pseudospectral collocation method. The 4:1 contraction case was solved using finite volumes. The results show that the steady-state solution is unique with respect to different initial conditions, the applied deformation history, and the diffusivity appearing in the equation for the differential velocity. The polymer concentration is not uniform in the flow field, since the polymer constituents are subjected to Fickian diffusion and stress-induced migration, the latter mechanism being responsible for the shear band formation. The total velocity develops a plug-like profile in the channel, with a low shear rate band near the center and a high shear rate band near the walls. In agreement with experiments [3], the flow rate exhibits a spurt at a critical pressure gradient. We will present first results on the impact of shear banding on the vortices in the contraction zone. As our model is relatively simple, it is a good candidate for more complex industrial flows. A Track Model for the Prediction of Ground-borne Vibration due to a Transition Zone

Matthias Germonpré*, Geert Lombaert**, Geert Degrande***

*KU Leuven, **KU Leuven, ***KU Leuven

ABSTRACT

Currently, several numerical models are available to predict ground-borne vibration due to railway traffic. Full 3D coupled finite element-boundary element models allow for a very detailed representation of the track and the soil. However, they require high computation time and modelling effort. Therefore, much research is done on developing computationally efficient methods which exploit the regularity of the problem geometry in the direction along the track. In a 2.5D approach, the track geometry is invariant in the longitudinal direction. This approach is computationally very efficient, but does not allow to include the periodic support of the rails by sleepers and the stress distribution under the sleepers is not correctly predicted. To overcome these restrictions, the track can be assumed to be periodic. Such models are still computationally efficient and allow to include parametric excitation due to the discrete rail support. However, they cannot include other types of track stiffness variations in the longitudinal direction such as transition zones, hanging sleepers or random track stiffness variations. Alternatively, more general track models have been developed that model the soil by a series of masses, springs and dampers. Despite their efficiency, these models don't allow for a direct prediction of the vibration transfer to the free field. In this presentation, a track model based on a wave analysis technique for multi-coupled periodic structures is presented [1]. The track is divided into periodic cells, corresponding to the sleeper bays. Each sleeper bay can be modelled differently. Part of the soil is modeled by finite elements and the waves in the soil travelling in the x- and z-directions are absorbed by perfectly matched layers [2]. This method is computationally much more efficient than full 3D models and it can be used to model any type of track stiffness variation. This approach is used to model different designs of a transition zone between a ballasted track and a slab track. The resulting train-track interaction forces and free field vibrations are compared. Finite Element Approximation for Thermal Electro Hydrodynamical Boussinesq Equations

Philippe Gerstner*, Vincent Heuveline**, Martin Baumann***

*University Heidelberg, **University of Heidelberg, ***University of Heidelberg

ABSTRACT

We consider the hydrodynamical behavior of dielectric fluids contained in a vertical cylinder annulus under applied voltage and temperature gradient between inner and outer wall. This setting gives rise to a body force, that is a superposition of buoyancy and dielectrophoretic force (DEP). The situation can be modeled by means of the thermal electro hydrodynamical Boussinesq equations (TEHD) which are based on the standard Boussinesq approximation for natural convection, augmented by DEP force and Gauss's law for describing the electric field inside the fluid as a function of temperature. Our method for approximately solving this set of equations is based on the Finite Element Method for discretization in both, space and time. For the spatial part, we make use of stable Taylor-Hood elements, whereas temporal discretization is implemented by a Petrov-Galerkin formulation with continuous trial and discontinuous test functions. In this way, the resulting discretized problem can be solved in a time-stepping manner, with an arising set of nonlinear algebraic equations for each time step which are solved by Newton's method. Here, the main computational effort lies in the solution of large-scale linear systems whose dimensions are in the order of several millions of variables when using a reasonable spatial resolution in 3D. To cope with these systems, we developed a parallel linear preconditioner which is based on a Schur complement approach for splitting the complete system into several subsystems according to the underlying physics of the model. These subsystems correspond to discretized elliptic problems, which are well suited for being solved with highly scalable methods. We make use of the Algebraic Multigrid Method and construct the way of solving the subsequent subsystems such that the overall solution process exhibits good parallel efficiency. In our talk, we present a computational study over the range of 384 to 4096 computing cores to demonstrate parallel efficiency of our method. Moreover, we present simulation results for different temperature gradients, leading to varying classical and electric Rayleigh numbers in the order of 10^3 to 10^4. The numerical solutions show a transition of a varying number of azimuthally to axially oriented vortices, where the latter are present in the final state of the dynamic system. Due to these vortices, radial heat transfer is enhanced as an increase of the corresponding Nusselt numbers show.

Column Collapse for Dense Granular Flows using the μ(I)-Rheology

Linda Gesenhues*, Fernando A. Rochinha**, José J. Camata***, Alvaro L.G.A. Coutinho****

*High Performance Computing Center and Department of Civil Engineering, Federal University of Rio de Janeiro, Brazil, **Mechanical Engineering Department, Federal University of Rio de Janeiro, Brazil, ***Computer Science Department, Federal University of Juiz de Fora, Brazil, ****High Performance Computing Center and Department of Civil Engineering, Federal University of Rio de Janeiro, Brazil

ABSTRACT

Non-Newtonian fluid behavior is typical for dense granular flow, as the particle concentration rises above a certain amount. Several rheology models can be used to cover this characteristic of the flow, which often happens to be viscoplastic. A model focusing on the viscosity description of dense granular flows is the so-called μ(I)-rheology. The μ(I)-rheology is based on the Coulomb friction, which states that normal stresses are proportional to the tangential stresses. Thus, the viscosity is related with a friction coefficient to the pressure. As a result of this, the friction coefficient is depending on the macroscopic and microscopic timescales of the particle rearrangement. This complex viscosity dependence on the friction coefficient results in a non-conventional viscoplastic shear-thinning behavior depending on the shear rate and the pressure. The models complexity leads to high nonlinearities and thus to oscillations, divergence and a high sensibility to input parameters. As a consequence, an appropriate regularization strategy, an adequate mesh and stabilization methods are inalienable. In this study, a 2D column collapse is simulated to analyze regularization and input parameters and their influence on the results. This parametric sensitivity study is conducted using the technique of design of experiments. We apply a Navier-Stokes solver coupled with a transport solver employing the volume-of-fluid method to describe the interface of the dense and light fluids (usually air). We use for the implementations libMesh, a C++ library that supports adaptive mesh refinement and coarsening and also interfaces with PetSc. The finite element formulation is the residual-based variational multiscale method. With libMesh, simulations are easily extended to three-dimensions. Experiences and challenges of the 3D simulation model are analyzed and discussed regarding the μ(I)-rheology. POULIQUEN, O., & FORTERRE, Y. (2002). Gradient-Based Computational Design of Microvascular Composites Based on an Interface-Enriched Generalized Finite Element Method

Philippe Geubelle*, Marcus Tan**, Stephen Pety***, Ahmad Najafi****, Scott White*****

*University of Illinois, **University of Illinois, ***University of Illinois, ****Drexel University, *****University of Illinois

ABSTRACT

Inspired from many living organisms, microvascular composites form a new class of fiber-reinforced polymeric matrix composites that contain a circulatory system made of an embedded network of microchannels. Based on the choice of the fluid circulating in the microvascular network, a wide range of multi-functionalities are being considered for these materials, including autonomic healing of internal damage, switching embedded antennas, and active cooling for high temperature applications. A recent development in the manufacturing of this class of composites, based on specially treated sacrificial fibers that are woven in the original fabric, undergo the composite cure cycle before undergoing a vaporization process, has led to the creation of microvascular networks that are integrated directly into the composite microstructure. This technology is being considered for a variety of active cooling applications, including skin materials for hypersonic aircrafts, actively cooling of car batteries and radiative cooling of nanosatellites. This new manufacturing process provides a lot of flexibility in the configuration of the embedded network. To assist with the material design process, a novel numerical tool based on an interface-based generalized finite element method (IGFEM) has been developed to model accurately and efficiently the impact of the coolant flowing through the microchannels on the thermal field in the composite. A gradient-based shape optimization scheme is then used together with the IGFEM solver to optimize the configuration of the embedded microchannel network based on a variety of objective functions and constraints. A key advantage of the IGFEM/gradient-based optimization scheme resides in the stationary nature of the non-conforming finite element mesh, which allows for the capture of evolving network shapes without facing the mesh distortion issues associated with classical FE-based shape optimization methods. Various 2D and 3D configurations of the microchannels are investigated and compared, based on their thermal and flow efficiency and on their impact on the structural integrity of the composite. We also optimize the microchannel network for redundancy. The predicted thermal impact of the optimized microvascular networks is compared with experimental observations obtained using infrared measurements. Tan, M. H. Y., Najafi, A. R., Pety, S. Machine Learning for Efficient Sampling in UQ

Roger Ghanem*, Christian Soize**

*University of Southern California, **Univesite Paris-Est

ABSTRACT

Uncertainty quantification is about relating the credibility of a decision to relevant available information. In the realm of mechanics, information is typically described in the form of constraints, such as conservation laws or boundary/initial conditions, and data. For settings where the associated physical processes evolve over several time or spatial scales, numerical treatments can become necessary which, when compounded with a probabilistic formalism for uncertainty quantification, become rapidly prohibitive. Recent methods of probabilistic learning developed by Soize and Ghanem, mine statistical information from data very efficiently, so much so that constraints can be delineated with only a handful of data points, or simulation runs. The procedure builds on diffusion manifolds, extracting an algebraic basis that localizes the data in an ambient space. A projected Ito equation is then used to sample on this manifold with an invariant measure synthesized from available data. Applications in many areas of science and engineering will be demonstrated.

Modeling Hemodynamics and Homeostatic Conditions in a Multiscale Fluid-Solid Growth Model of the Pulmonary Arterial Tree (Part II)

Hamidreza Gharahi*, Seungik Baek**, Vasilina Filonova***, C. Alberto Figueroa****

*Michigan State University, **Michigan State University, ***University of Michigan, ****University of Michigan

ABSTRACT

Pulmonary arterial hypertension (PAH) is a complex vascular disease associated with elevated pulmonary arterial pressure. PAH is a multi-factorial phenomenon in which the onset and early progression of the disease can be traced to permanent changes in vessel composition, geometry, and/or stiffness of the distal vasculature tree. Although clinical catheterization pressure measurements and high resolution medical images are typically readily available, current medical imaging modalities are unable to provide insight on the disease progression in the downstream vasculature. Therefore, any modeling effort must account for the role of the distal arterial tree geometry on global pulmonary hemodynamics and vascular growth and remodeling. Moreover, a key component of fluid-solid growth formulations [1] is the establishment of homeostatic (e.g. equilibrium) baseline states. The objective of the present work is to derive a methodology to define homeostatic states in the distal pulmonary arterial tree based on an extension of Murray's law and steady state hemodynamics. We constructed a multi-scale model of the pulmonary arterial tree, whereby each vessel was modeled as a 0D segment endowed with a bio-chemo-mechanical growth and remodeling model. Using an extension of Murray's law [2], each vessel radius and wall compositions were determined as a target state via a minimization problem involving the metabolic cost of maintaining the blood volume, the power needed to overcome viscous drag by the blood flow, and the metabolic cost of the vessel wall constituents under the constraint of mechanical equilibrium. The minimization problem was coupled with a steady state hemodynamic description of the arterial tree. The coupled problem produced the composition of the arteries in the arterial tree as well as their geometry. Using the small on large theory [3], the stiffness of each individual blood vessel can then be calculated from their composition. References [ ] C. A. Figueroa et al., Comput. Methods Appl. Mech. ABSTRACT

Two-dimensional Van der Waals (vdW) bilayers are emerging class of materials for their unique opto-electronic and mechanical behavior. Bilayer stacking takes place through the mixing and matching in between semimetals (e.g., Graphene), semiconductors (e.g. transition metal dichalcogenides (TMDs)), and insulators (e.g., hexagonal boron nitride; h-BN). TMD bilayers are most popular due to their practical applications in electronics. TMDs possess a wide variety of tunable opto-electronic properties such as the position of band gap, indirect–direct band gap crossover, harmonic generation, valley pseudospin effects. In addition, lattice mismatch in two different monolayers ensures the possibility of its use as transistors and diodes. Among several existing growth techniques, epitaxial growth mechanism is the most preferred one due to its technological advantages such as reduction of defect density, consistency in the overall growth, growth products with sharper interfaces, the perseverance of in-plane electrical conductivity via the introduction of mirror twin grain boundaries, and simultaneous reduction of tilt grain boundaries. Our experimental group developed a new two-step epitaxial growth technique in order to generate WS2-WS2 homobilayer. In their current technique, first step is the formation and isolation of the orientation controlled (metal terminated or chalcogenide terminated) WS2 monolayer followed by the second step involving orientation dependent second layer growth. Therefore, it is important to perform computational analysis in order to shed light towards this orientation controlled two-step epitaxial growth mechanism. Density Functional Theory (DFT) approach has been implemented in order to gain knowledge on the structural and electronic properties of WS2 homobilayer and WS2-WSe2 heterobilayer. At first, we computed equilibrium interlayer distances and verified with the experimental data. In order to investigate the nature and strength of the interlayer interactions, various combinations of AA, AA', AB and AB' stacking are considered and the most stable combination is chosen based on formation energy. Analysis of charge transfer, Density of States (DOS) provide insight into the nature of bonding. Moreover, possible presence of dangling bonds around the edge is predicted from the charge distribution. Significant in-plane strains and out-of-plane displacements are introduced in WS2-WSe2 heterobilayer due to interlayer interactions. Various alignments of WS2-WS2 and WS2-WSe2 bilayer structures are studied in terms of different degree of relative rotation angle between the layers. Our results provide guidelines for experimental design of the two-step epitaxial growth technique to synthesize TMD homobilayers and heterobilayers.

Optimization Under Uncertainty for Complex PDE Models in High Dimensions

Omar Ghattas*, Peng Chen**, Umberto Villa***

*The University of Texas at Austin, **The University of Texas at Austin, ***The University of Texas at Austin

ABSTRACT

We consider optimization problems governed by PDEs with infinite dimensional random parameter fields. Such problems arise in numerous applications: optimal design/control of systems with stochastic forcing or uncertain material properties or geometry; inverse problems governed by stochastic forward problems; or Bayesian optimal experimental design problems with the goal of minimizing the uncertainty or maximizing the information gain in the inferred parameters. Standard Monte Carlo evaluation of the objective results in a number of PDE constraints equal to the number of samples. The resulting many-PDE-constrained optimization problem, while deterministic, is nevertheless prohibitive to solve, especially when the PDEs are "complex" (large-scale or nonlinear or coupled) and when the parameter space is high-dimensional (as occurs after discretization of an infinite-dimensional field). We present high-order derivative-based approximations of the parameter-to-objective maps that--in combination with randomized rank-capturing algorithms--exploit the structure of these maps (geometry, smoothness, low effective dimensionality). Their use as a basis for variance reduction is demonstrated to significantly speed up Monte Carlo sampling, leading to scalable solution of several stochastic optimization problems governed by turbulent flow and wave scattering with up to O(10^6) uncertain parameters. 1. ABSTRACT

Composites are complex material systems that exhibit physical behavior simultaneously on multiple time and spatial scales. The serviceability and failure properties of devices made out of composites exhibit a range of variability that reflects this complexity and their dependence on the details of the manufacturing process. Prognostics and efficient design of these devices requires reliance on computational tools capable of coupling across physical phenomena as well as across space and time scales. Additional requirements often add the need for a probabilistic analysis that further exacerbates the computational burden, often rendering it prohibitive. In this talk, we will demonstrate the application of new methodologies for probabilistic learning that serve to distill intrinsic structure from a handful of numerical simulations and sample additional realizations , as needed, that are consistent both with this structure and the statistics of the few initial samples. This methodology was recently developed by Soize and Ghanem and is applied in the present context to an integrated multiscale and multi physics simulation setting. The procedure begins by discovering the intrinsic structure using the method of diffusion manifolds. Following that, a stochastic Ito equation is developed that samples on this manifold, producing, at minimal cost, additional samples that are consistent with the initial set.

Robust Optimization in Training Neural Networks

Amir Gholami*, Zhewei Yao**, Kurt Kuetzer***, Michael Mahoney****

*University of California, Berkeley, **University of California, Berkeley, ***University of California, Berkeley, ****University of California, Berkeley

ABSTRACT

There has been renewed efforts in using machine learning to tackle engineering problems. However, the training algorithms used to learn a representation of the problem is often times susceptible to adversarial perturbation. Solutions to these, require analysis and modification of the state-of-the-art optimization algorithms, along with designing robust models. In a typical machine learning task, one is given a set of input data $\x$ with the corresponding response y, drawn from an unknown distribution $\mathcal{P}$. In practice, we only observe a set of discrete, noisy examples drawn from this distribution. Then the model is trained, often times with stochastic gradient descent, to learn this distribution. An open question is how much, if at all any, has the model learned from the distribution after the training is finished, and what is the uncertainty associated with that? This is an important aspect that has to be analyzed before these methods could be used for solving physical problems, or aid in modeling. In practice, it has to been shown to be trivial to create adversarial perturbation to the inputs of a neural network so that it produces wrong results with very high confidence. This adversarial perturbation can even be performed on models that have very high accuracy and using more training data often times does not help either, which underscores the importance to design new optimization methods to make the model more robust. One approach to address this problem is to use robust optimization instead of minimizing for the average case. In this method, one optimizes for the worst case at every iteration of the optimization. This essentially changes the minimization to a min-max problem. It can be shown that robust optimization reduces both the bias as well as the variance in the generalization error. In this work, we perform a Hessian based analysis of the adversarial training and analyze how the landscape of the objective functional changes when the network is solved with robust optimization vs when it is solved with vanilla stochastic gradient descent.

Numerical Simulation of Counterstreaming Plasma Interactions Using a Multifluid Model

Debojyoti Ghosh*, Christos Kavouklis**, Thomas Chapman***, Richard Berger****, Genia Vogman*****

*Lawrence Livermore National Laboratory, **Lawrence Livermore National Laboratory, ***Lawrence Livermore National Laboratory, ****Lawrence Livermore National Laboratory, *****Lawrence Livermore National Laboratory

ABSTRACT

Counterstreaming plasma interactions are an important phenomenon in inertial confinement fusion, where irradiation of the hohlraum with laser beams results in plasmas ablating off the hohlraum surfaces and the fuel capsules and interacting with each other. Related high-energy density physics experiments involve interactions of plasmas ablating off discs irradiated by lasers. Simulating such flows with multispecies hydrodynamic codes [1] can result in unphysical solutions due to the use of a single velocity field. Kinetic approaches [2], on the other hand, are prohibitively expensive for experimental-scale simulations. In this talk, we report on the development of EUCLID (Eulerian Code for pLasma Interaction Dynamics) based on a multifluid approach. The Euler equations are solved for each ion species and the electrons. The species interact through electrostatic forces, friction, and thermal equilibration. This model allows for distinct flows for each species through their separate velocity fields. The electrostatic potential is obtained from the charge densities using the Poisson equation. The equations are discretized on a three-dimensional Cartesian grid using a conservative finite-difference formulation, and the interface fluxes are computed using the 5th order WENO scheme. The Poisson equation is solved using a 6th order method. In addition, adaptive refinement of the mesh around regions of strong interactions is implemented using Chombo [3], a library for solving PDEs on block-structured AMR grids. The disparate masses of electrons and ions result in a stiff system of semi-discrete ordinary differential equations in time. We use the semi-implicit additive Runge-Kutta methods for time integration, where the electron acoustic modes are integrated implicitly in time, while the remaining terms in the ions and electron equations are integrated explicitly. We present the verification of EUCLID for several benchmark test cases, as well as the simulation of counterstreaming plasmas. In particular, we show that our approach is able to accurately capture plasma interpenetration when frictional forces are small, and the fluids do not converge to a single fluid within experimental time scales. ABSTRACT

Introduction: Transcatheter Aortic Valve Replacement (TAVR) has emerged as a life-saving solution for inoperable elderly patients with calcific aortic valve (AV) disease, often as their only life-saving treatment [1]. However, failed delivery due to tortuous aortic geometry, valve migration, and paravalvular leaks (PVL) lead to increased stroke risk, increasing the overall morbidity and mortality post-TAVR. There are numerical studies that attempted to address these complications, but the focus was only to deploy the TAVR valves, thus neglecting their post-deployment performances during heart beating. This study proposes a fluid-structure interaction (FSI) simulation to evaluate a TAVR valve's performance by comparing its hemodynamics, PVL, and thrombogenicity with healthy and diseased aortic valves in Simulia Living Heart Human Model (LHHM). Methods: LHHM is an electro-mechanical model of heart function in which a self-expandable TAVR valve crimping and deployment procedures were simulated using finite element (FE) method. The FE solver was Abaqus Explicit. The TAVR stent equipped with the prosthetic leaflets in the deployed configuration was then used for FSI analysis. Specifically, the LHHM inner ventricular surface contraction was implemented as boundary condition. A body-fitted sub-grid geometry resolution (SGGR) method was chosen during the FSI fluid solution. The SGGR approach starts with a cartesian grid from which a geometry is subtracted to maintain a curvilinear boundary, hence ensuring body-fitted mesh. The deployed valve's structural mechanics and blood flow were modeled in Abaqus Explicit and FlowVision respectively. A 2-way strong implicit coupling was used between these two partitioned solvers using FlowVision Multi-Physics Manager. Thrombogenic potentials were calculated from probability density function of flow stress accumulation (SA) along multiple platelet trajectories [2]. Platelet motion was modeled using a transient two-phase flow simulation in ANSYS Fluent Discrete Phase Model, where the spherical particles mimic platelets. Results: The surrounding tissue stress and strain values were lowest when the stent was deployed more towards ventricular side, hence determining the optimal implantation zone. The FSI simulations of a TAVR valve in LHHM along with a healthy and diseased AV allowed us to compare their hemodynamic and thrombogenic performances. Discussions: TAVR valve structural performances during successive cycles of beating heart were successfully evaluated. The suggested numerical methodologies can ultimately pave the way for minimizing the risk of clinical complications by enhancing pre-procedural planning. ABSTRACT

Two-dimensional (2D) materials are monolayer crystals and only one atom or a few atoms thick. Two-dimensional multilayer materials (2DMMs) are made of a parallel stack of 2D materials and their mechanics are the main focus of this work. Mono- and multi- layer 2D materials possess exceptional and coupled mechanical, electrical, and thermal properties. Due to their ultra-thin membrane-like geometries and a high degree of crystalline arrangements they show rich nonlinear elasticity and elastic-buckling. The promise of 2D materials has fostered intense research leading to an expansion of this family of materials. Like graphene, other single layer 2D materials, such as Molybdenum disulfide, also behave like the thinnest nonlinear-elastic membranes having stiff in-plane and ultra-weak bending rigidity, leading to distributed buckles like wrinkles, ripples, or folds. 2DMMs have another level of complexity due to weak van der Waals interactions between neighboring layers, which interplays with the rigidity of individual layers resulting in complex deformation morphologies. Ripples and wrinkles and the ensuing elastic strain in monolayer and multilayer Molybdenum disulfide can alter their electronic properties and can also yield other properties like tunable surface leading to various high-impact applications. Therefore, understanding and predicting the mechanical instabilities of multilayer Molybdenum disulfide is crucially important problem. Herein a continuum model is utilized to quantitatively predict the deformation mechanism, the onset of mechanical instabilities and transition between different complex periodic buckled shapes for Molybdenum disulfide (MoS2). Further, the role of van der Waals interaction and the role of interlayer slide are also investigated. The computational results obtained in this work show very good agreement with the available experimental results.

Mathematical Modelling of Water-flooding Techniques in Heterogeneous Hydrocarbon Reservoirs

Tufan Ghosh*, G. P. Raja Sekhar**, Debasis Deb***

*Indian Institute of Technology Kharagpur, **Indian Institute of Technology Kharagpur, ***Indian Institute of Technology Kharagpur

ABSTRACT

Fractured carbonate reservoirs are potential resources for crude oil and natural gas. These reservoirs are composed of matrix block with interconnected network of fractures. Oil or gas recovery from such low porosity and low permeability reservoirs are important because a large amount of such hydrocarbon fluids are trapped inside those reservoir formulations. Water-flooding or more specifically spontaneous imbibition is most effective recovery mechanism to increase the production from fractured reservoirs. However, the performance of water-flooding mainly depends on the wettability of the reservoirs. In co-current imbibition, the wetting phase displaces the non-wetting phase in such a way that the non-wetting phase moves in the same direction of the wetting phase. Hence the corresponding mathematical model requires a total flux condition. This study deals with the mathematical modeling of co-current spontaneous imbibition for heterogeneous porous reservoirs. We assume that the flow is governed by the multi-phase extension of Darcy equation, where the saturation of the local wetting phase satisfies a diffusion type of equation with an additional term from the counter-current phenomena. The study assumes that the wetting and non-wetting phases flow in the same direction, and hence the sum of Darcy's velocities (i.e. net flux) is assumed to be non-vanishing. The model is used to identify the difference in the recovery fraction between homogeneous and heterogeneous reservoir formulation. The resulting governing equations are highly non-linear in nature and have been solved numerically. We have used different porosity variation models based on the existing literature, say, exponential and inverse-linear. It has been shown that the co-current imbibition recovery is very much sensitive to the viscosity ratio, porosity variation models and the wettability of the reservoir. Effect of the viscosity ratio on the water saturation gradient and the end point mobility ratio is also studied. In addition the consequences of the nature of heterogeneity and wettability of the medium on the sweeping efficiency of co-current imbibition are investigated.

ABSTRACT

The eXtended Finite Element Method (XFEM) [1] has been used in Cast3m [2] to simulate static and dynamic problems of crack propagation in elastic and elastic-plastic materials. In this method, the decorrelation of the crack description and structure mesh is particularly adapted to incremental propagation strategy when the crack path is not known a priori. As a first point and in the context of non-linear behaviour, over-integrated elements are used [3]. As a second point the use of local propagation criteria implies an accurate description of physical quantities (stress, strain, internal variables ...) in a limited area around the crack front. Hence a priori ignorance of the propagation path forces us to use a very fine mesh of enriched elements in a rather large zone. As a consequence of these two points, the cost of this method increases drastically for engineer-sized problems. Thus we decided to develop a hierarchical Adaptive Mesh Refinement tool (AMR), to ensure that the mesh is always sufficiently fine at vicinity of the crack front during the propagation. This tool was demonstrated to work well with the X-FEM method and limits the calculation time by restraining the number of fine enriched elements to a small area. In this paper the algorithmic procedure used to simulate a crack propagation with the X-FEM method coupled with an AMR tool in Cast3m is described in detail. More particularly the presentation focuses on two important steps of this procedure: 1) the refinement algorithm for standard and enriched elements, 2) and the method used to transfer the mechanical fields from one mesh to another between two steps of propagation, especially when those fields are described with an enriched discretization. The efficiency of the method is illustrated by application cases of crack propagation in elastic-plastic media in 2 and 3 dimensions. First results fit experimental data. [1] J.C. PASSIEUX, J. ABSTRACT

Polymer composites are currently used in a variety of applications, such as aerospace, electronics, recreation, infrastructure, light-weight vehicles, and alternative energy generation. The rational design of advanced composites for these applications requires that data, models and measurements be used together toward specific composites performance goals, such as manufacturability, multi-functionality, environmental durability, and toughness. This presentation will cover three examples where such an integrated approach has accelerated and advanced the understanding of fundamental issues that drive the rational design of advanced composites. First, our recent advancements in the use of modelling to understand the role of surface chemistry on the properties of nanocellulose polymer composites will be reviewed; second, the modelling of mechanochemistry for understanding the interfacial damage reported by fluorescent probes will be summarized; and finally, we will report on our investigation of the novel mechanical properties of self-assembled cellulose nanocrystals (CNCs) in the helicoidal, or Bouligand structure. Such materials possess high mechanical strength and toughness, similar to bone, the mantis shrimp dactyl club or ivory, and are toughened by a combination of soft, energy-dissipating polymer and the Bouligand ordered-fiber structures. In this presentation, we will report additional simultaneous enhancements in the in-plane modulus, strength, elongation, toughness and out-of-plane flexibility of the Bouligand films by including small amounts of a longer CNC material. The mechanical properties we report in the blended films are some of the best reported for self-assembled CNC materials thus far. Using coarse grained molecular dynamics simulations of binary CNC systems we identify the role of the high aspect ratio CNC phase to be to enhance interaction strengths by maximizing CNC-CNC overlap lengths.

Analysis of Three-Dimensional Transient Channel Flow at Moderate Reynolds Numbers

Marco Giometto*, Parviz Moin**, George Park***, Adrian Lozano-Duran****

*Columbia University, **Stanford University, ***University of Pennsylvania, ****Stanford University

ABSTRACT

The law-of-the-wall, scaling laws, and reduced-order models established largely for equilibrium turbulent boundary layers should not be assumed to be directly applicable to non-canonical wall-bounded flows. Turbulent boundary layers with mean-flow three dimensionality are one class of such non-canonical flows, with particular relevance to external aerodynamics and hydrodynamics. In these flows, the mean flow direction changes continuously across the shear-layer thickness due to the cross-stream pressure gradient induced by the geometry of the immersed body. Fundamental questions remain unanswered with regard to changes of wall-turbulence structure with the imposition of additional rates of mean strain. Using direct numerical simulation, we study temporally developing three dimensional turbulent boundary layers in a planar channel at friction Reynolds numbers from 186 up to 934 subjected to a range of spanwise forcing. This flow is well suited for the study of non-equilibrium effects due to its simple geometry. We propose an inner and outer scaling of the problem that well collapses turbulent statistics across the range of considered Reynolds numbers. We also show how rapid pressure perturbations reduce wall-normal velocity variance via pressure strain effects, yielding the observed Reynolds stress deficit during the initial transient. An analysis of the effects of variable spanwise forcing magnitude on the Reynolds stresses will also be proposed and interpreted in light of predictions from rapid-distortion theory.

A Monolithic Coupled Solver for Large Scale Simulations of Hydraulic Fracture

Bianca Giovanardi*, Anwar Koshakji**, Raul Radovitzky***

*Massachusetts Institute of Technology, **Massachusetts Institute of Technology, ***Massachusetts Institute of Technology

ABSTRACT

Hydraulic fracturing of rock by the injection of a pressurized fluid is a common technique used to release formerly inaccessible hydrocarbons. 3D simulations of realistic scenarios need to tackle the complexity arising from the nonlinear hydro-mechanical coupling and from the large scale of oil reservoirs. A suitable simulation algorithm must then exhibit massively parallel scalability in order to conduct analysis with the necessary resolution in a reasonable time. We present a computational framework for the coupling of the fractured rock's mechanics with the fluid flow in the cracks, governed by Reynolds lubrication equation. The discretization consists of a hybrid discontinuous Galerkin finite element formulation for the rock, which enables the description of the crack opening between adjacent mesh elements explicitly, and a continuous Galerkin finite elements discretization for the fluid problem, formulated on mesh interfaces. After showing that a naïve staggered attempt to treat the coupling is unstable under inflow boundary conditions for the fluid, we present a robust monolithic iterative algorithm. The resulting system of strongly nonlinearly coupled equations is assembled and solved in parallel, exploiting the iterative solvers implemented in the open source library PETSc. Results in good agreement with well-known semi-analytic solutions available in literature are discussed, with particular focus on performance in terms of accuracy and scalability.

Uncertainty Quantification for Complex Systems in High Dimensions Using Grassmann Manifold Variations and Machine Learning

Dimitris Giovanis*, Michael Shields**

*Johns Hopkins University, **Johns Hopkins University

ABSTRACT

This paper proposes a novel adaptive method for performing uncertainty quantification of high-dimensional (input and output) stochastic systems. This method addresses the limitation of the recently proposed method [1] used for uncertainty quantification of systems with high-dimensional responses, where the Delaunay triangulation limits the method to problems of modest stochastic dimension (less than about 6). In this paper, we abandon the multi-element nature of the aforementioned method by eliminating the need for discretizing the input parameter space. This is achieved by using spectral clustering [2] which, refers to a class of machine learning techniques that utilizes the eigen-structure of a similarity matrix to partition data into disjoint clusters based on the similarity of the points, in order to effectively identify areas of the parameter space where sharp changes of the solution field are resolved. In order to do this, we derive a similarity matrix based on the pairwise distances between the high-dimensional solutions of the stochastic system projected onto the Grassmann manifold. The distances are calculated using appropriately defined metrics and the similarity matrix is used in order to cluster the data based on their similarity. For each cluster, the points that are most far apart between all the points of the cluster are used as seeds and new samples are generated at their proximity which is defined based on statistical properties of the cluster. This way we populate with samples areas of the parameter space where sharp changes of the response field are resolved.

ABSTRACT

Reliability of electronic devices is still a main concern for aeronautics, military and space industries. In any electronic device, the bare Printed Circuit Board (PCB) is considered as a carrier which provides interconnection between components. During the last decades, PCB technologies have strongly evolved to fulfil increased manufacturers requirements. Nowadays, OEM, PCB manufacturers and research laboratories are closely collaborating to assess PCB reliability and lifetime. To achieve that goal, it is fundamental to characterize precisely base materials in order to anticipate failure. With precise models, it is expected that finite element calculations will be able to reproduce PCB aging under environmental constraints for example… In the present work, we focus on the numerical predictions of the elastic behaviour of thin woven composites. The microstructure characterization, mechanical tests and numerical models were performed on the real material used for PCB, so it is expected that the combined experimental and numerical strategy will provide accurate predictions. The in-plane properties are measured by carrying out classical uniaxial testing. Strains are evaluated with digital image correlation. Nevertheless, the out-of-plane elastic properties cannot be captured due to the thickness of the laminate (a few hundred of microns). From the literature, it is well established that the knowledge of the out-of-plane properties is fundamental to investigate the lifetime of high density printed circuit boards. A two stage homogenization method is developed to obtain the overall elastic orthotropic behaviour of a woven composite. Inputs as internal structure and measured in-plane elastic properties are needed. A first homogenization focuses on the behaviour predictions of the yarns. In a second stage, a representative volume element is reproduced in Abaqus software. For high frequency applications, the matrix is made of a resin filled with a large volume content of ceramic inclusions. Since the behaviour of the matrix phase is unknown, an inverse method is proposed. The methodology has been applied at different temperatures in the range [-55°C; +125°C]. Finally, numerical simulations of a plated through hole in a double sided PCB will be presented. By considering the material properties obtained from datasheet or deduced from the present work, it is shown the major importance of the temperature dependency of out-of-plane properties on the lifetime of a printed circuit board. Optimal Truncation of Unbounded Anisotropic Elastic Computational Domains

Dan Givoli*

*Technion - Israel Institute of Technology

ABSTRACT

A common procedure for solving wave problems in unbounded elastic domains (such as problems in geophysics) is to truncate the unbounded domain via an artificial boundary, and impose an Absorbing Boundary Condition (ABC) on that boundary, with the hope of generating as little as possible spurious reflection. In this study, an optimal low-order ABC is proposed for time-dependent waves in anisotropic elastic media. This ABC enjoys the following advantages: (a) it is fully compatible with the standard finite element displacement formulation, (b) it yields a symmetric finite element formulation, (c) it is easy to implement, (d) it is proved to be strongly (energy-) stable for all anisotropic media, even for those that give rise to "inverse modes", in which the phase and group velocities have opposite signs, and (e) in typical cases it is more accurate than the well-known Lysmer-Kuhlemeyer ABC (except for isotropic media, where LK is optimal among first-order ABCs). The objective function associated with the optimal ABC is the energy-rate reflection coefficient, which is always less than unity for all media and all types of propagating waves. The success of the new ABC is demonstrated via numerical examples.

Results from DoD HPCMP CREATE(TM)-AV Kestrel for the 3rd AIAA High Lift Prediction Workshop

Ryan Glasby*, J. Taylor Erwin**, Douglas Stefanski***, Steve Karman****, Kevin Holst*****

*University of Tennessee, **University of Tennessee, ***University of Tennessee, ****Pointwise, Inc., *****University of Tennessee

ABSTRACT

HPCMP CREATE™-AV Kestrel computational fluid dynamics (CFD) component COFFE is applied to Tasks 1 – 3 of the 3rd AIAA High Lift Prediction workshop. In task 1, a series of P2 tetrahedral meshes for the NASA High-Lift Common Research Model were used to carry out flow-field versus mesh size studies at various angles of attack. In Task 2, P2 fully tetrahedral medium-fidelity meshes for the JAXA Standard Model with and without the nacelle/pylon were used to evaluate the accuracy of computed aerodynamic output as compared to experimental data for an angle of attack sweep. In Task 3, a series of P1 quadrilateral meshes was utilized to obtain the mesh convergence properties for a DSMA661 (MODEL A) airfoil at a fixed angle of attack, subsonic, high Reynolds number condition. A variety of turbulence models were employed for these computations, and the CFD solver in conjunction with the higher order meshes demonstrated the capability to accurately predict the flow-field surrounding a commercial aircraft in a high-lift configuration.

High-Order Accurate Time Integration Methods for Inductive Heating Analysis

Tobias Gleim*, Detlef Kuhl**

*University of Kassel, **University of Kassel

ABSTRACT

An important concept in metal forming processes is local heat treatment and cooling that influence local material properties, such as ductility, hardness, yield strength, or impact resistance, see K. Steinhoff, U. Weidig and N. Saba (Functionally Graded Materials in Industrial Mass Production, 35-52, 2009). Cold forming methods by means of electromagnetic forces are also of great scientific interest, in order to obtain special shapes and product properties. To make these techniques more effective in industry, or to optimize its application, corresponding numerical simulation tools are needed. One of the main topics of these manufacturing processes is characterized by the electromagnetic-thermal influence. The inductive heating of a metal shaft is influenced by an alternating current inducing a high frequency electromagnetic field, which causes a temperature increase due to the resulting eddy currents. In order to examine this process, the fully coupled electromagnetic Maxwell equations are combined with the temperature field in a monolithic approach. Due to the high frequencies of the applied current and the strongly temperature dependent material parameters, the investigated set of temporal and spatial second order differential equations are strongly non-linear. Thus, adequate material models as well as proper numerical schemes have to be established. Therein, the focus will be on the application of high-order accurate numerical schemes in combination with appropriate error estimators, see T. Gleim (Universität Kassel, Ph.D. Thesis, 2016). These electromagnetic-thermal equations are numerically solved using the finite element method in space, time integrations schemes and Newton-Raphson method. The main focus of the talk is the high-order accurate time integration of the semidiscrete, second order ordinary differential equation. Therefore, high-order accurate Runge-Kutta schemes, see J. C. Butcher (Mathematics of Computation, Vol. 18, 50-64, 1964), and discontinuous and continuous Galerkin schemes, see T.J.R. Hughes and G.M. Hulbert (Computer Methods in Applied Mechanics and Engineering, 339-363, 1988), T. Gleim (Universität Kassel, Ph.D. Thesis, 2016), with an controllable order of accuracy are investigated. Representative examples demonstrate the numerical properties, advantages and disadvantages of the studied integration schemes.

Design and Optimization of Tubular Chassis for a Competition Vehicle

Dany Godinez*, Fernando Velazquez**

*Unam, **Unam

ABSTRACT

This research is about the use of topology optimization method applying in a chassis design for student's competitions but no limited to this; it can apply in small commercial vehicles which are based in tubular chassis. The initial body is modeled using plane surfaces, which are modified via topological optimization to define the best material distribution in the body, which satisfies the needs of the competition. Some surfaces are restricted as no design surfaces to keep critical parts of the structure. It has been proposed four load cases assuming of chassis behavior along the road and considering dynamical load factors. The optimization objective is to maximize structural stiffness, while volume is reduced until 10% of the original volume. Symmetry and thickness of the optimized surfaces are controlled, looking for well-defined geometries instead of ambiguous material paths. After this a tubular structure is designed using the optimal structure as guide. Finally, the new structure is evaluated vie FEA to verified its performance.

Adjoint Topology Optimization of Mold Cavity Cooling Channels

Stephan Goeke*, Olaf Wünsch**

*University of Kassel, **University of Kassel

ABSTRACT

Many industrial tools, like mold cavities, need internal channels with cooling fluids to remove excess heat. The achievable temperature change, or the amount of heat that can be removed, depend on several factors. The geometric influence to the performance consists on the one hand on their relative position to the surface under thermal load and on the other on the overall shape of the cooling channels. The performance of the shape does depend on contributions from both conduction and convection. Fluid flow and heat transfer in the solid must hence be solved in a coupled fashion to ensure the local fluid flow is accurately incorporated into the optimization. The aim of this contribution is to showcase a method to apply topology optimization to this problem. The optimality is gauged by a uniformity objective function for the temperature at a surface heated by a constant heat flux. A uniform surface temperature leads to a prolonged tool life since thermal stresses due to temperature differences are minimized. Due to the complex conjugate system a gradient based approach in form of the continuous adjoint method is chosen and implemented into the Software OpenFOAM. The adjoint equations for topology optimization of conjugate heat transfer systems are shown and the resulting gradients validated for both modes of transport. A level-set is used to differentiate between the different regions. The method is illustrated for pure conduction problems of filling a design space with two materials of different thermal properties. In addition the combination with fluid flow and the resulting convection dominated heat transfer system is analysed. Here the optimization highly depends on the treatment of the pressure loss. Different methods for handling this multi objective optimization problem are presented. Karpouzas, Georgios & De Villiers, Eugene. (2014). Level-Set based Topology Optimization using the Continuous Adjoint Method. OPT-i 2014 - 1st International Conference on Engineering and Applied Sciences Optimization, Proceedings.

From Macroscale to Microscale: Inferring 3D Model Parameter Distribution Using Digital Cameras and Inverse Algorithms

Sevan Goenezen*, Yue Mei**

*Texas A&M; University, Mechanical Engineering Department, College Station, TX, **Texas A&M; University, Mechanical Engineering Department, College Station, TX

ABSTRACT

Additive manufacturing has recently regained attention and benefits from dramatic increases in computational resources and performance that was not available in its early developmental stages. In this presentation, we will make use of supercomputing resources to solve inverse problems in elasticity, and in particular to solve for model parameter variability throughout the sample that are likely to occur in additive manufacturing. In the first part of the talk, we will focus on macro-scale mechanics at scales ranging from orders of millimeters to meters. We will show for the first time that it is feasible to infer information about the interior model parameter distribution in three dimensional space for a given constitutive model, knowing solely displacements on the surface of the specimen. No assumptions will be made about the interior of the specimen and the model parameters will be assumed to be unknowns on the finite element mesh nodes and linearly interpolated throughout the domain using tetrahedral finite elements. Our problem domain will have several hundreds of thousands of unknown model parameters. The inverse problem is posed as a constrained minimization problem, where measured displacement data is correlated to computed surface displacement data under the influence of a regularization term that stabilizes the model parameter distribution due to measurement noise. The computed displacement data depends on the model parameter distribution and satisfies the equations of equilibrium, solved using in-house written finite element methods. Despite of the fact that the minimization problem is solved using an adjoint scheme that reduces computational cost drastically, OpenMP platforms together with MPI computations are introduced in an effective approach to obtain computational results in a reasonable time. Surface displacements can be conveniently determined from digital image correlation or other optical techniques using regular digital cameras. Knowing the model parameters will provide information about the additive manufacturing process and help optimize process parameters. In the second part of this talk, we will analyze feasibility to recover the crystallographic orientation of grains and their anisotropic mechanical property distribution using displacement fields obtained from digital camera images.

A Linear Solver Framework for Oil Reservoir Simulation

Paulo Goldfeld*, Douglas Augusto**, Luiz Carvalho***, Cesar Conopoima****, Leonardo Gasparini*****, José Rodrigues******, Michael Souza*******

*UFRJ, **Fiocruz, ***UERJ, ****UFJF, *****Petrobras, ******Petrobras, *******UFC

ABSTRACT

As with many other applications, the need for high-performance computing in Oil Reservoir Simulation is driven by ever more refined meshes and by the necessity of multiple simulations in the context of optimization and/or uncertainty quantification. The single most costly computational task and the most difficult one to parallelize is the solution of the large linear systems arising in the Newton iteration at each time step. Despite the large selection of freely available parallel linear solvers, we found that reservoir simulation software presents enough specificities as to justify the development of a dedicated solver. One such example is a block matrix format that allows for non-homogeneous block sizes. Such a matrix arises, for instance, when using AIM (adaptive implicit method), and is not supported by standard libraries such as PETSc or Trilinos. As design baselines, we opted for hybrid MPI/OpenMP parallelism and our plan, as future developments, is to use OpenACC to take advantage of accelerators. Another interesting feature of our software is a framework for the implementation of parallel algorithms using data flow concepts, which hides much of the complexity related with communication. We will present some key aspects of the solver development and discuss numerical results obtained with matrices from real simulations of multiphase flow and geomechanics, focusing on performance and scalability.

ABSTRACT

We address numerical simulation aspects of dispersive periodic media, where dispersion is introduced by micro-scattering effects. Instead of explicitly modeling the micro-scatters into the unit cell we make use of a micropolar (Cosserat) continuum with independent micro-rotational degrees of freedom directly translating into additional wave modes responsible for the dispersive response. We formulate–in a finite element sense– a wave propagation problem for the micropolar media and determine the dispersion relationships for a unit cell. This characterization is possible after assuming spatial periodicity and studying a single cell with the aid of Bloch-Floquet theorem to impose suitable boundary conditions at extreme faces of the cell. The resulting implementation is later used to find the dispersion curves for homogeneous and porous micro-polar solids. The introduction of kinematic variables and in particular, the addition of micro-rotations, results in additional propagation modes in the form of micro-rotational waves. At the same time, the micro-rotations also cause classical shear waves to propagate dispersively and to couple with the new micro-rotational waves. In this talk we focus in simulation aspects related to wave propagation problems in such a periodic micro-polar medium. First we derive general finite element equilibrium equations yielding discrete equilibrium relations for forces and moments. The general formulation is then implemented to address micropolar cellular materials making use of the theory of phononic crystals. Our presentation is organized as follows: - Fundamentals of Bloch analysis in periodic media. - Review of the micropolar model. - Bloch analysis for the micropolar model. - Results: numerically obtained dispersion curves for several microstructures. The study of wave propagation and dispersion relations for phononic crystals where the constituents are Cosserat solids is of interest in the study of cloaking elastodynamics. While the equations are invariant for electromagnetic waves , it has been shown that in the case of elastic bodies the equations are not invariant. Additional requirements, related with micro rotations, exist in this case, and the equations that satisfy the invariance are termed Willis equations. These can be expressed as Cosserat elasticity under some assumptions.

ABSTRACT

In this work we explore the possibilities of reduced order modeling for augmented reality applications. We consider parametric reduced order models based upon separate (affine) parametric dependence so as to speedup the associated data assimilation problems, which involve in a natural manner the minimization of a distance functional. The employ of reduced order methods allows for an important reduction in computational cost, thus allowing to comply with the stringent real time constraints of video streams, i.e., around 30 Hz. Examples are included that show the potential of the proposed technique in different situations.

Variational Derivation of Reciprocal Mass Matrices for Isogeometrical Analysis via Localized Lagrange Multipliers

José A. González*, K. C. Park**, Ján Kopacka***, Radek Kolman****, Sang-Soon Cho*****

*Universidad de Sevilla, **University of Colorado Boulder, ***Institute of Thermomechanics, Czech Academy of Sciences, ****Institute of Thermomechanics, Czech Academy of Sciences, *****Korea Atomic Energy Research Institute

ABSTRACT

The authors proposed in a previous work [1] a variationally consistent method for the derivation of reciprocal mass matrices for FEM formulations in structural dynamics. The approximation was based on a judicious combination of the variational form of Hamilton's principle with a parametrized consistent-lumped structural mass matrix and the enforcement of interface constraints with localized Lagrange multipliers. High accuracy and efficiency of the obtained reciprocal mass matrices was demonstrated for structural transient and vibration problems. This new contribution constitutes an extension of our previous work to the field of Isogeometrical analysis, adapting the techniques used to derive reciprocal mass matrices in FEM to the particularities of B-spline and NURBS-based methods. In particular, two isogeometric methods are investigated: classical B-spline approximation and Bézier extraction techniques. Furthermore, dispersion analysis is the tool adopted to tune the parametrized reciprocal mass matrices for optimal accuracy. Finally, the reciprocal mass matrices are incorporated into explicit time integration schemes to solve classical benchmark problems and evaluate the efficiency and precision of these new isogeometrical approximations of the inverse mass matrix. Error Indicator for Polygonal Finite Element Meshes in 2D and 3D

Octavio Andrés González-Estrada*, Sundararajan Natarajan**, Juan José Ródenas***

*Universidad Industrial de Santander, **Indian Institute of Technology – Madras, ***Universitat Politècnica de València

ABSTRACT

Introduction: Arbitrary polygonal meshes in finite element approximations provide advantages in terms of meshing flexibility and accuracy, compared to traditional finite element formulations. They relax mesh conditions related to mesh distortion, and easily manage transition elements. However, as any numerical approximation, they exhibit an error which should be controlled in order to validate the numerical results in practical applications. In this work, we present strategies to quantify the discretization error in polygonal meshes, in 2D and 3D, using the Zienkiewicz-Zhu error indicator. Methods: The accuracy of recovery-based error indicators is strongly related to the quality of the recovered stress field used to evaluate the error energy norm. To recover the stress field, we propose different strategies: nodal averaging and moving least squares smoothing. It is also possible to further improve the quality of the recovered stresses by imposing equilibrium conditions. The proposed technique is applicable to smooth and singular problems by means of stress field splitting. Results and conclusions: The error estimator has been tested with smooth and singular problems having exact solution. The results in the 2D and 3D benchmark problems show a highly accurate recovered stress field, with a performance of the indicators comparable to standard finite elements. The convergence of the error indicates that the proposed error indicator is asymptotically exact and can be used to perform h-adaptivity in polygonal meshes. References [1] O. A. González-Estrada, S. Progressive Damage Failure Analysis (PDFA) for Compression Strength After Impact (CSAI) Simulations Using an Enriched Shell Element

Tyler Goode*, Mark McElroy**, Mark Pankow***

*North Carolina State University, **NASA Johnson Space Center, ***North Carolina State University

ABSTRACT

Composites are becoming pervasive in many aerospace and automotive applications for their higher relative performance. One major challenge with using composite materials in these applications is their susceptibility to damage resulting from transverse loads such as low-velocity impact (LVI). Historically, certification of composite parts has relied heavily on experimental testing, but recent advancement in progressive damage failure analysis (PDFA) for composites has demonstrated damage models with suitable accuracy [1]. The major drawback of using these state-of-the-art models is the need for a high-fidelity mesh resulting in excessively long simulation times. To mitigate this problem, a novel shell element enriched with the Floating Node Method (FNM) and a damage algorithm based on the Virtual Crack Closure Technique (VCCT) has been developed that captures complex damage mechanisms such as delamination propagation and transverse matrix cracks while exhibiting runtimes up to two orders of magnitude faster than existing high-fidelity models [2]. In this work we will model the multi-step process of LVI and compression strength after impact (CSAI) using this enriched shell element [2]. The two-step process will be simulated to ensure that the damage is transferred correctly from one step (LVI) to the next (CSAI) correctly. The computational model will be verified and validated against existing computational data by AFRL [3]. The models are investigated for various energies and laminate stacking sequences. Finally, it will be correlated against an existing high-fidelity PDFA model to understand how the response compares in both prediction and in computational time. This work will enable efficient large-scale simulations of full structures with accurate estimations of damage and strength predictions. [1] S. B. Clay and S. P. Approximating Eigenvalue Clusters Using Filtered Subspace Iterations

Jay Gopalakrishnan*, Luka Grubisic**, Jeffrey Ovall***

*Portland State University, **University of Zagreb, ***Portland State University

ABSTRACT

The FEAST algorithm is a popular eigenvalue solver in numerical linear algebra, known for its multiple layers of parallelism. The algorithm targets a cluster of eigenvalues enclosed within a contour. It can be viewed as a subspace iteration applied to an operator-valued contour integral. When used to approximate a part of the spectrum of an unbounded differential operator, it is typical to discretize the operator. When the algorithm uses the discretized operator, several basic questions arise: Does it converge? If so, does the limit subspace approximate the true eigenspace of the unbounded operator? When a higher order discretization is used, does the error in eigenvalues decrease at correspondingly higher orders? In this talk, we present a framework that allows us to answer these questions. Conclusions are drawn under a resolvent approximation condition. We then verify this assumption for the Discontinuous Petrov Galerkin (DPG) method. The new convergence results will be illustrated through numerical examples.

Some Observations on Parameter Estimation in Strongly Coupled Fluid-Structure Interaction Problems

Peter Goransson*, Jacques Cuenca**, Timo Lahivaara***

*KTH Royal Institute of Technology, **Siemens Industry Software, ***University of Eastern Finland

ABSTRACT

We study the problem of inverse estimation of model parameters in resonant, acoustic fluid-structure interaction (FSI) problems over a wide frequency range 1-1000 Hz. These problems are subjected to local minima, which represents a major obstacle in the field of parameter identification. The acoustic fluid as well as the solid are modelled using the 1D wave equation, and the parameters used in the estimation are their respective speeds of sound and loss factors. The type of cost functions studied are based on the frequency response, of a field variable or a quantity derived from these. In the current work the L2-norm between a target and a model solution is used, and in order to capture the FSI effects, the power radiated into the acoustic fluid from the vibrating solid is used. The estimation is performed through different methods including gradient based optimisation, Bayesian Markov chain Monte-Carlo, and non-linear least squares. The occurrence and the background of local minima are discussed, and the performance of the different solution methods evaluated for different strengths of the coupling between the solid and the fluid. In addition, the influence of the amount of damping present in the two media will be illustrated. The correlation between different model parameters is analysed and shown how these correlations control the local minima. In the presentation, various approaches to finding the global minimum, i.e. the true model parameters, will be discussed and their effectiveness will be evaluated.

A Fokker-Planck Expansion of Jump Processes

Hossein Gorji*

*MCSS, Mathematics Department, EPF Lausanne

ABSTRACT

The dynamics of a Markovian system can be described in general by jump and diffusion processes. The aim of this talk is to discuss how a jump process governed by the Master equation can be reduced to a Fokker-Planck operator describing a diffusion process, consistently. In particular, we focus on the Fokker-Planck approximation of the Boltzmann equation for a monatomic gas. Therefore in the resulting diffusion process, the state of the particles evolve along continuous stochastic paths. That brings computationally favourable characteristics, since here no collision is performed and thus relatively coarse spatio-temporal resolutions may be employed. In fact, the effect of collisions on the dynamics of the distribution is projected to continuous stochastic forces acting as drift and diffusion. The drift and diffusion coefficients are then closed through the velocity moments of the Boltzmann operator, together with the H-theorem. The convergence of the devised Fokker-Planck approach is studied for the case of the BGK approximation of the Boltzmann equation. Furthermore, practical results for the case of reentry flows together with plume setups are presented.

*University of Michigan, **Sandia National Laboratories, ***Sandia National Laboratories, ****Sandia National Laboratories

ABSTRACT

We consider the problem of propagating uncertainty through computational simulation models of varying fidelities. Our goal is to estimate, or predict, certain quantities of interest from a specified high-fidelity model when only a limited number of simulations are available. To aid in this task, lower fidelity models can be used to reduce the uncertainty of the high-fidelity predictions. We propose to frame this problem as learning a latent variable network structure for the statistical independence relationships between the models from available simulation data. First a latent variable model is posed for each simulation model under consideration, then a network structure between the models is learned, and finally predictions are made for the output of the highest fidelity model. We demonstrate how existing techniques, such as control variate Monte Carlo and recursive co-kriging, can be interpreted as particular realizations of this framework. Furthermore, we consider both the tasks of learning the graph structure and parameters of the conditional probability distributions. Finally, we describe an experimental design procedure targeted towards reducing the uncertainty of our predictions. Examples are provided for both synthetic and physics-based simulations.

ABSTRACT

Vibrating systems may encounter catastrophic failure due to resonance or flutter induced by time-varying disturbances and loading. To ensure safety and proper functionality, several vibration control techniques are available to mitigate or suppress these phenomena. In this work, an active vibration control (AVC) technique is adopted. The most popular AVC techniques developed in the recent years are the state-space based linear quadratic regulator (LQR) and H-infinity control techniques. These techniques, however, become simply ineffective for large-scale systems. To address this computational bottleneck, the physical-space based robust and minimum norm quadratic partial eigenvalue assignment (RQPEVA and MNQPEVA) techniques are proposed in the literature. In contrast with the most popular state-space based AVC techniques, the RQPEVA and MNQPEVA techniques work exclusively on the second-order model obtained by applying the finite element method on the vibrating systems. Furthermore, the RQPEVA and MNQPEVA techniques suppress only the problematic/resonant modes of vibration and guarantee the no-spillover property of the remaining large number of modes. In this work, a brief review of the LQR, H-infinity, and MNQPEVA techniques, with an emphasis on their relative computational advantages/drawbacks, is presented first. A comparative study of the three control techniques with respect to their computational effectiveness and applicability. Next, comparative study in terms of economic efficiency is presented for three systems: a small-scale (2 degree of freedom), a medium-scale (900 degree of freedom), and a large-scale (1 million degree of freedom), which are representative of various structural systems, and are subjected to a recorded data from the 1986 San Salvador earthquake. It is observed that, for large-scale systems, the MNQPEVA technique is computational more effective and economic as compared to the LQR and H-infinity techniques. In the second part of this work, we consider the effects of uncertainties that are invariably present in practice in the external disturbances and the damped natural frequencies of vibrating structures, especially of large-scale dynamic systems. Based on MNQPEVA technique and an optimization under uncertainty (OUU) scheme, a computationally efficient control methodology for large-scale systems is presented. The proposed scheme will be useful for economic design and to significantly lessen the probability of extreme failures with catastrophic consequences. A novel scheme based on hierarchical clustering and importance sampling is developed for accurate and efficient estimation of the probability of failure which is an essential ingredient in successful implementation of the proposed OUU scheme. A numerical example is included to illustrate the proposed approach.

Statistical Analysis of the Void Structure of Bi2Sr2CaCu2Ox Multifilamentary Superconducting Wires and Its Effect on the Critical Current Density

Xiaofan Gou*, Xinxin Zhou**

*Hohai University, **HOhai University

ABSTRACT

High temperature multifilamentary composites Bi2Sr2CaCu2Ox/Ag/Ag-alloy (Bi2212) are the only round wires (RWs) for a potential candidate with sufficient critical current density (Jc) for fabricating high field magnet. Very complex microstructures of Bi2212 RWs, especially a large number of voids or gas bubbles in Bi2212 superconducting filaments, is believed to have strong impacts on the current-carrying and thermal diffusion of whole wires. In this article, we first statistically analyzed the size and distribution of voids in filaments using the reported microscopic data, obtaining the essential statistical regularities. An electrical model was further developed to predict the Jc of multifilamentary wires while taking into account of the current limiting mechanisms of the void structure in filaments, and the current sharing roles of filament to filament bridges. Our model predicts the quantitative dependence of Jc on the number of Bi2212 filaments in each bundle of a double-restack wire and porosity. Our results are useful optimizing design and fabrication of Bi2212 multifilamentary wires.

Key words: LBM, Bubbles, Mural Boundary, Interaction

Abstract. *Complex interaction force is produced due to the effect of the coupling between the bubbles and mural face.In this paper, a three dimensional gas-liquid-solid coupling danamics model is adopted, and the optimized block-grid technology is applied to this model.Based on the viscous fluid theory, the lattice boltzmann equation to describe the movement of gas-liquid is bulit, at the same time the half-way bonce back model in LBM and the comnination of finite deference is adopted to deal with the solid wall boundary.First, verify the correctness of the model using the classical Laplace's law. Then, the coupling characteristics of the single bubble and the solid wall and the surface solid wall are studied respectively. The solid wall boundary condition has obvious law to the surrounding pressure and the velocity field. Then studied Eo and Mo's impact on the results under the condition of* $\gamma = 1.0$.

1 INTRODUCTION

The interaction between solid wall and bubbles and has extensive engineering application background and significance to scientific research.Whether to the studies to the cavitation bubble on the propeller [1, 2], the explosion bubble near the ship[3, 4], and atmospheric pressure air bubble [5] in the piping, all need air bubble in a flow field detailed understanding and grasp of the dynamic characteristics of.Due to this problem involves many and strong nonlinear coupling effect, its become the research hotspot and difficulty in related field.Although, there are a lot of experimental studies on bubble dynamics. 1978 Clift [6], such as review of gravity using within the scope of different fluid properties under the buoyancy of the shape of the bubble.Bhaga etc. [7] in 1980 studied the different number of Morton (Mo) and Renolds number (Re) under the condition of air bubbles in the process of floating shape, drafting and speed of change.Duineveld [8] and Zhang[9] studied through experiments respectively within bubbles and bubbles, and the coupling phenomenon of bubbles and free surface. But limited by the fluid properties the complex dynamics (such as viscosity, surface tension, etc.), it is unable to carry on the accurate control, resulting in many air bubbles under the condition of the research cannot be done through experiment.But it did not stop the footsteps of people continue to explore the bubble movement characteristics, with the development of computational fluid dynamics (CFD), the researchers found that by combining experimental research and numerical study way can solve this problem very well. And with a variety of excellent numerical algorithm is proposed, and the emergence of high performance computer, numerical simulation in the study of dynamics of bubble has played a more and more obvious role.Gas-liquid, gas-solid or liquid-solid research has made many significant achievements, but the study of gas- liquid-solid three phaseS coupling is relatively less, and mainly focused on the coupling of bubble and infinite solid wall and the coupling effect of bubbles and tiny particles.In 2001, Popinet etc. [15]studied the bubble pulsation and jet near the tablet process. In 2006, Yang, etc. [16]made the review of the coupling of liquid ,bubbles, and the particles in the mixed solution . In 2011, Hassan, Amaya and Ghosh, [17 - 19] studied the single and multiple bubbles movement characteristics under the conditions of the different diameter and Angle of long tube.The two types of research is a common feature of bubble size and the size of the border is not in the same scale, which ignores the boundary and the boundary between the complex coupling phenomenon.

In this paper, using the lattice Boltzmann method based on free energy model, established the viscous flow field in the bubbles with scales coupling model of complicated boundary. To achieve the accuracy of capturing the gas liquid two phase boundary , two groups was introduced to the model in the Boltzmann equation, through multi-scale, which can respectively Navier - Stokes equations of second order accuracy and Cahn Hilliard equation. Rigid boundary flow processing used the previous work [20] of lattice Boltzmann complex boundary processing method On this basis, this paper studies single bubbles with different characteristics than with boundary and the interaction characteristics of surface boundary edges and corners in the same scales, including velocity field and pressure field

around the bubble. Respectively according to the above two kinds of solid wall boundary, the calculation and analysis of the different fluid properties Mo, Eo condition for coupling characteristics are studied.

2 THEORY

2.1 Govering Equation

Based on viscous fluid mechanics theory, for a Newtonian fluid in constant temperature,and incompressible flow field, the dynamic characteristics of air bubbles can be described through a set of Navier - Stokes (navier-stokes) equations and Cahn Hilliard equation:

$$\partial\rho / \partial t + \nabla \cdot (\rho \mathbf{u}) = 0 \tag{1}$$

$$\partial(\rho \mathbf{u}) / \partial t + \nabla \cdot (\rho \mathbf{u}\mathbf{u}) = -\nabla \cdot P + \mu \nabla^2 \mathbf{u} + \mathbf{F} \tag{2}$$

$$\partial\theta / \partial t + \nabla^2 \cdot (\theta \mathbf{u}) = \varpi \nabla^2 \psi\theta \tag{3}$$

Among them, the first two equations represents the traditional navier-stokes equation and rho, u, represent the density of fluid in the flow field velocity vector and fluid viscosity, F is the body force, including gravity, P for thermodynamic pressure for an ideal system, P0 can calculate including a state equation:

$$P_0 = \nabla \cdot (\rho c_s^2) \tag{4}$$

In the equation, c_s is the sound velocity of grid, $c_s = 1/\sqrt{3}$. In the ideal gas system, equation (4) can be revised to:

$$P = P_0 + \theta\nabla\psi_\theta = \nabla \cdot (\rho c_s^2) + \theta\nabla\psi_\theta \tag{5}$$

θ is for tracking interface defined by the order parameter, its evolution process, such as equation (3), namely Cahn Hilliard equation, including ϖ is diffusion coefficient. Based on the free energy of lattice Boltzmann model, bits of theta is thickness of border with gas liquid two phase (W),surface tension coefficient (σ), the order parameter (θ), as well as the free energy density function related parameters of the chemical potentia[22]:

$$\psi\theta = \frac{12\sigma\theta^3}{W\theta^{*4}} - \frac{3\sigma}{W\theta^{*2}}(4\theta + \frac{W^2}{2}\nabla^2\theta) \tag{6}$$

And the $\theta^* = \frac{(\rho_L - \rho_G)}{2}$, ρ_L, ρ_G respectively the density of the liquid and the gas phases.

2.2 Lattice Boltzmann Method

According to Lee, the research into [23],LBM can be used to discrete the Navier - Stokes equations :

$$f_i(\mathbf{x}+\mathbf{c}_i\delta_t, t+\delta_t) = f_i(\mathbf{x},t) + \frac{1}{\tau_n}(f_i^{(eq)}(\mathbf{x},t) - f_i(\mathbf{x},t)) + \mathbf{F} \tag{7}$$

Among them, i said discrete grid direction, this paper adopts D3Q19 model, i= 0-18. The c_i, $f_i(\mathbf{x},t)$ respects discrete grid speed and discrete volume force. Said delta t time step, tau n is relaxation coefficient. $f_i^{(eq)}(\mathbf{x},t)$ is to meet maxwell distribution. The equilibrium state of the particle distribution function for ideal fluid without considering $f_i(\mathbf{x},t)$, by choosing suitable $f_i^{(eq)}(\mathbf{x},t)$, through multi-scale expansion operation, and meet the following constraints [24],

$$\sum_i f_i^{(eq)}(\mathbf{x},t) = \sum_i f_i(\mathbf{x},t) = \rho \tag{8}$$

$$\sum_i f_i^{(eq)}(\mathbf{x},t)\mathbf{c}_i = \sum_i f_i(\mathbf{x},t)\mathbf{c}_i = \rho\mathbf{u} \tag{9}$$

$$\sum_i f_i^{(eq)}(\mathbf{x},t)\mathbf{c}_{i\alpha}\mathbf{c}_{i\beta} = (\theta\psi_\theta + c_s^2\rho)\delta_{\alpha\beta} + \rho\mathbf{u}_\alpha\mathbf{u}_\beta \tag{10}$$

By (8) can meet the second-order precision degree to [25] the navier-stokes equations,

$$f_i^{(eq)} = \omega_i \cdot [\frac{P_0}{c_s^2} + \rho(\frac{\mathbf{c}_i \cdot \mathbf{u}}{c_s^2} + \frac{(\mathbf{c}_i \cdot \mathbf{u})^2}{2c_s^4}) - \frac{\mathbf{u}^2}{2c_s^2}] \tag{11}$$

Among them, the ω_i is the weight coefficient of particle distribution along the direction of discrete grid, $\omega_0 = 1/3, \omega_{1,6} = 1/18, \omega_{7,18} = 1/36$. P0 can be obtained by (4). For gas liquid two phase flow system, due to considering the effect of boundary effect, Shu [22, 24] to (11) on the right side of the first revised and perfected. If $\omega_i \cdot \frac{P_0}{c_s^2} = \omega_i l \cdot A_i$, is for the revised A_i,

$$A_0 = 3\rho(1-2c_s^2) - 6\theta\psi_\theta \tag{12}$$

$$A_{1,18} = 3(\theta\psi_\theta + c_s^2\rho) \tag{13}$$

3 MODEL

In this paper, the implementation of the process, the gas-liquid-solid system is divided into gas-liquid gas boundary and solid-liquid boundary of these two subsystems.Unified the lattice Boltzmann unit system, namely the $\delta_t = 1, \delta_l = 1$.

3.1 Solid-Liquid Boundary

Boundary processing method based on rebound has second order accuracy of model,

building a virtual boundary layer in the fluid-structure interaction. Combined with shi' extrapolation method get accurate macroscopic velocity on the virtual boundary.In this method, fluid particles near the border of rebound in the virtual boundary. And formula system of speed is no longer used by the actual speed of the solid wall boundary,it is the speed of the virtual boundary. In this way, it can ensure that the occurrence of collision point with the speed to collect in the same position.

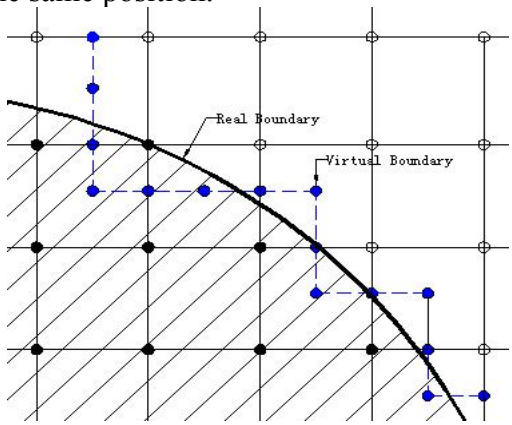

Figure1-the sketch of the curved boundary condition

In this model, the border of fluid particles specific migration process is shown in Figure 1.In Figure 1 heavy line is the location of the actual solid wall boundary,In the connection of 1/2 in virtual node structure, in turn, connect the virtual node, constitute the virtual boundary in Figure 1.

$$f_i(\mathbf{x}_f, t+\delta_t) = f_i^{(eq)}(\mathbf{x}_f, t) - 6\omega_i\rho(c_i \cdot \mathbf{u}_{mid}) \tag{14}$$

$\mathbf{x}_f$ is closest to the solid wall of the fluid particle position, i for direction in the opposite direction of I, it indicates that the rebound in the aftermath of the particles collide with the wall. $\mathbf{u}_{mid}$ said $\mathbf{x}_f$ with its most adjacent solid particle position x_s connection speed of the center.

3.2 Gas-Liquid Boundary

By building another set of lattice Boltzmann equation can be solved by Cahn Hilliard equation, tracked the gas-liquid boundary. Compared with the traditional sense of the structure of the lattice Boltzmann equation, namely, regardless of volume force (7), in 2002, Succi etc. [27] put forward a consideration of particle transfer efficiency between adjacent lattice fixed format.

$$g_i(\mathbf{x}+c_i\delta_t, t+\delta_t) = q \cdot g_i(\mathbf{x}, t) + (1-q) \cdot g_i(\mathbf{x}+c_i\delta_t, t) + \frac{g_i^{(eq)}(\mathbf{x}, t) - g_i(\mathbf{x}, t)}{\tau_\theta} \tag{15}$$

Among them, the $g_i(\mathbf{x},t)$ also said the particle number density distribution function, and $f_i(x,t)$, at the same time the macroscopic variables of the order parameter theta. Tau theta is the coefficient of relaxation in the lattice Boltzmann equation, q is control of particle transfer efficiency between lattice parameters. $q = \frac{2}{1+2\tau_\theta}$

When q = 1, (14) can be converted into traditional lattice Boltzmann equation.

4 RESULTS AND DISCUSSION

4.1 Veritfy the model

First of all, using classical Laplace's law to verify the correctness of the bubble dynamics model is established in this paper. For the unified description of fluid properties, this paper defines three dimensionless parameters of Eo and Mo, Re [22].

$$Eo = \frac{4g(\rho_L - \rho_G)R^2}{\sigma} \tag{16}$$

$$Mo = \frac{g(\rho_L - \rho_G)\mu_L^4}{\rho_L^2\sigma^3} \tag{17}$$

$$\mathrm{Re} = \frac{2\rho_L V_{end} R}{\mu_L} \tag{18}$$

μ_L is the liquid viscosity coefficient, R is bubble radius, V_{end} is the ultimate speed of floatation bubble is smooth, the other parameters to ensure consistent with defined on.

Relevant calculation parameters for: computational domain size is 120 * 120 * 120, bubble radius $R = 20$, $\tau_\rho = 0.6$, $\tau_\theta = 0.75$, the gas bubble wall thickness W = 5.0, Γ = 100, Eo = 15.984, M o = 0.03083. According to the law of Laplace, balance when the surface tension and the internal and external pressure difference of bubble:

$$\Delta P = \left|P_{in} - P_{out}\right| = \frac{2\sigma}{R} \tag{19}$$

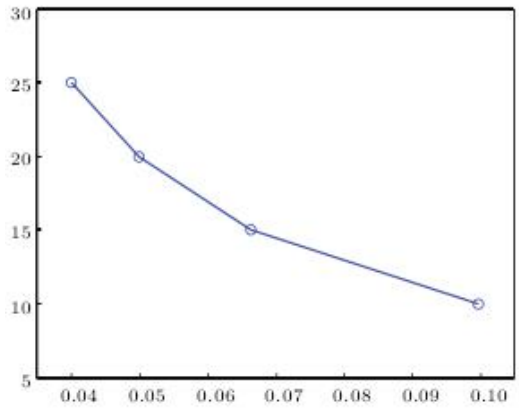

Fig.2 Under the condition of different Mo,
numerical validation of the pressure difference inside and outside ΔP and R

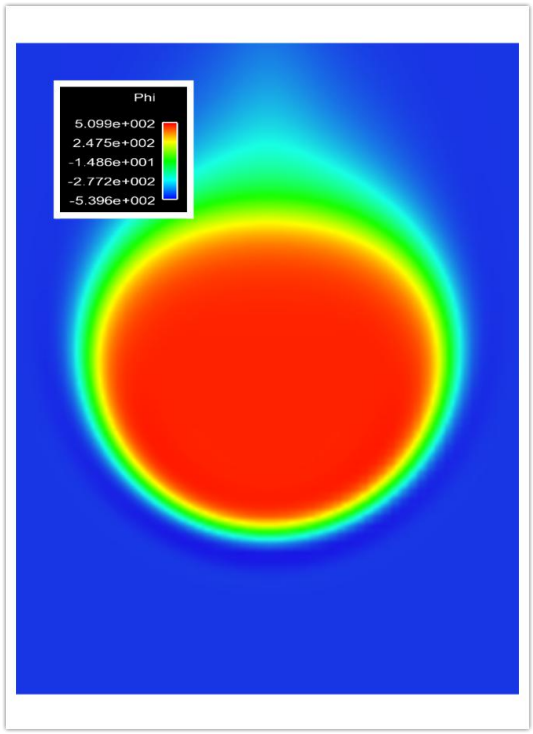

Fig.3 the density for the rising bubble

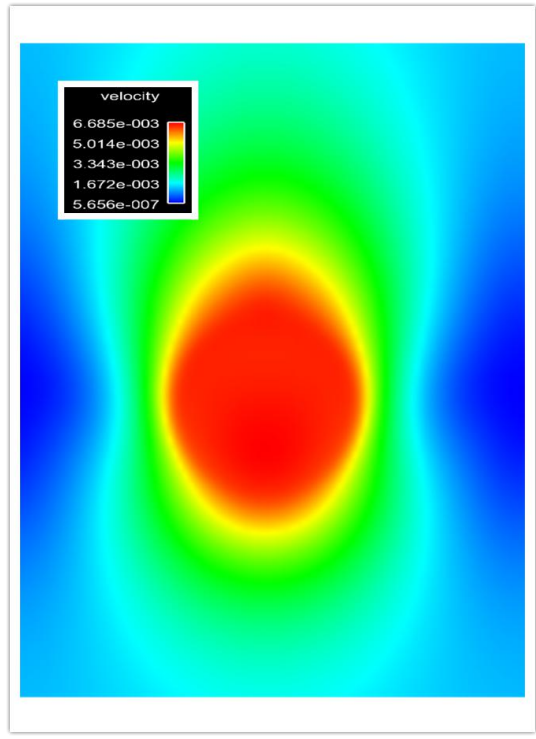

Fig.4 the velocity for the rising bubble

To verify this model is matched with the theoretical value, the paper respectively simulation experiment under the condition of the Eo = 15.984, R = 10, 15, 20, 25, the corresponding Mo = 0.1973, 0.0877, 0.0493, 0.0316 when bubbles as the pressure difference between the inside and outside the delta P, as shown in figure 2. Can be found from the figure 2, measurements from this model were in good with the theoretical value, further verified the model's ability to capture gas-liquid boundary.

4.2 The interaction between the boundary and the bubble

In the process of calculainfluence on the results, and then, studied, Eo and Mo's impact on the results under the condition of γ=1.0.

Figure 5 records the bubbles in the jet flow field around throughout throughout t = 30000 steps before and after t = 40000 steps two typical moments of stress field distribution. The black thick lines in the graph said bubble contour line in the cross section. In figure 5 (a) can be clearly observed that the bubble is formed between the solid wall of high pressure water cavity, and due to drainage phenomenon on the edge of the bubble formation of the low pressure area. Figure 5 (b) not only shows the jet through after the initial stage of the flow field of pressure distribution and the gradient direction, and can be observed after the reconstruction of smooth surface bubbles.

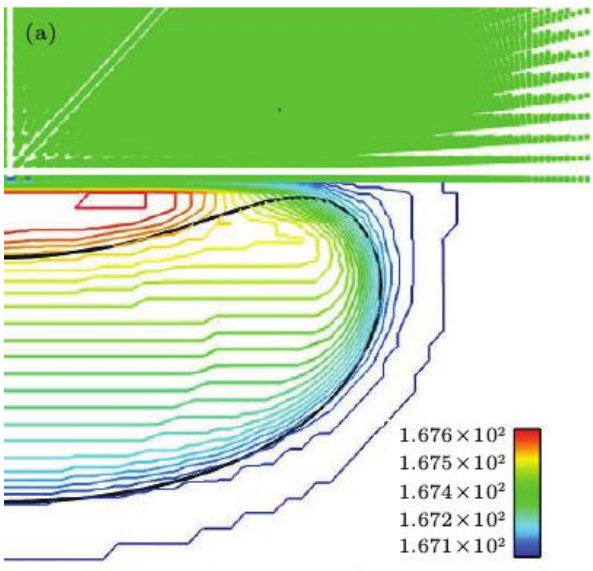

Figure5 (a) the pressure profile Bubble around flow field Bubble (t=30000 steps)

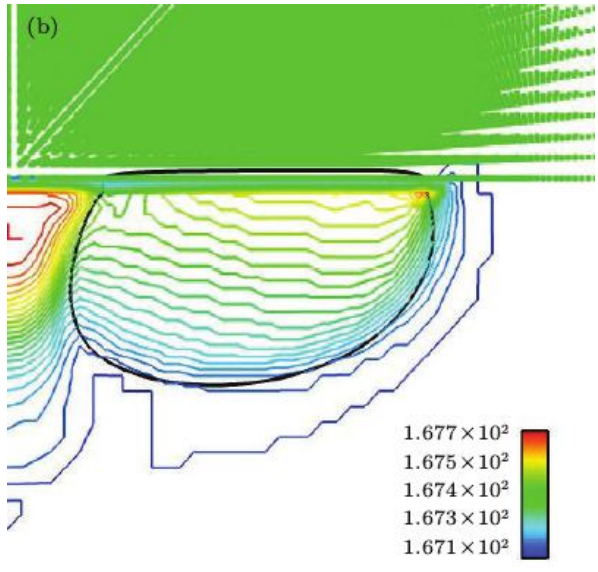

Figure5 (b) the pressure profile Bubble around flow field Bubble (t=40000 steps)

Figure 6 records the stress field distribution surrounding bubble ,the before and the after from being the circular bubble. The heavy line said bubble contour lines, thin lines for pressure equipotential line, the cloud picture for stress nephogram.From figure 6 (a) that can be observed in the bubbles on the surface to form a high, at the edge of the high produce obvious phenomenon of pressure drop, this is mainly due to the water cavity fluid in the outside, and cause the local pressure drop. On both sides of the bubble below the partial form symmetrical low pressure area, this is mainly due to the buoyancy bubbles driven flow field around the movement caused by the formation of the vortex ring [7].From figure 6 (b), the formation of circular bubble around the floating process of the spherical structure, the inside of the solid wall adjacent position relative to other higher pressure. The existence of the pressure on the one hand, will squeeze the bubble inside, cause its flat, on the other hand caused the increase of bubble ring inside diameter on the ways to level, ensure the bubble ring would be able to bypass the spherical structure.

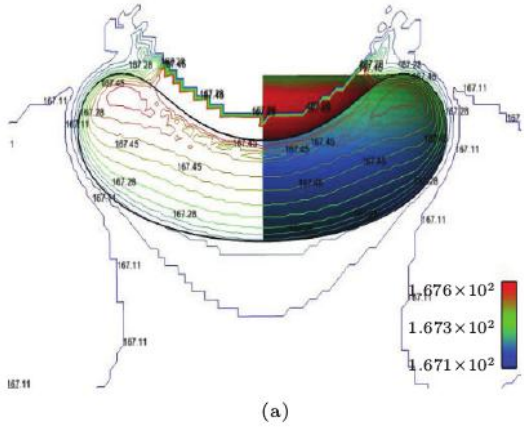

Figure6 (a) bubble surrounding pressure field distribution, before and after a circular bubble (t=15000steps)

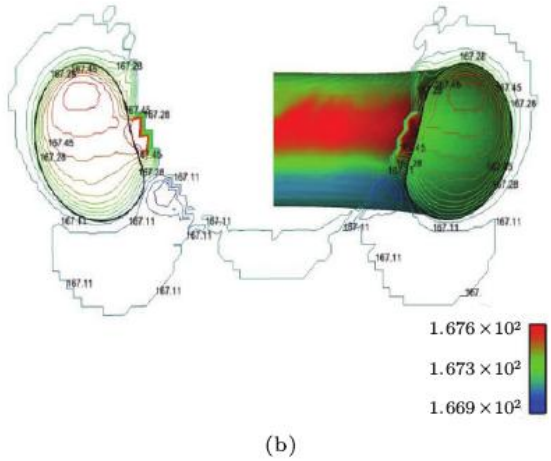

Figure6 (b) bubble surrounding pressure field distribution, before and after a circular bubble (t=20000steps)

4.3 The influence of Mo,Eo

In order to further study the effects of fluid properties on coupling rule, keep the feature sizes than $\gamma = 1.0, \rho_L = 1000.0, \rho_G = 1.0, \tau_\theta = 0.75$, the section to calculate the different Eo, M o under the condition of air bubbles movement characteristics, specific parameter values are shown in table 1.

Table1 Fluid property parameter values

τ_θ	τ_n	σ	Mo	Eo
0.75	0.7	2.0	0.49328	15.985
	0.75	2.0	1.20237	15.985
	0.8	2.0	2.49723	15.985
	0.61892	1.0	0.49328	31.970
	0.64865	1.0	1.20237	31.970
	0.67838	1.0	2.49723	31.970

5 DISSION

- -Based on the early stage of the solid boundary, gas-liquid convection boundary treatment, on the basis of the lattice Boltzmann research will be improved model of gas liquid two phase flow of 2 d to 3 d, and combined with complicated boundary grid Boltzmann processing method, studies the same scales bubbles with considering the effect of edge plane and solid wall surface coupling properties of the solid wall.
- -In feature sizes than certain cases, the surface tension coefficient and fluid property parameters on the coupling process between bubble and curved wall also has an important influence.
- -More research about the multi-bubbles need to be studied.

Nonlinear Simulations and Global Stability Analysis for Fluid-Structure Interaction, With Application to Flag Flapping

Andres Goza*, Tim Colonius**, Erick Salcedo***, Phillipé Tosi****

*Princeton University, **California Institute of Technology, ***California institute of Technology, ****California Institute of Technology

ABSTRACT

Immersed boundary and interface methods do not require fluid meshes that conform to the structural domain, and are therefore promising candidates for simulating fluid-structure interaction (FSI) problems where the structure has a non-canonical geometry or is undergoing large-amplitude motion. These methods lead to a large nonlinear system of equations to enforce the fluid-structure coupling. These nonlinear equations are typically solved iteratively with either a block Gauss-Seidel procedure or a Newton-Raphson method, and there are challenges to implementing either approach efficiently: the former leads to inexpensive evaluation of a single iteration but can require dozens of iterations to converge, whereas the latter converges in a small number of iterations but has a large cost per iteration. We discuss an immersed-boundary (IB) method that inherits the fast convergence behavior of a Newton-Raphson method while retaining the small computational complexity of a block Gauss-Seidel procedure. This IB method is strongly coupled, and accounts for nonlinearities in the fluid, the structure, and the coupling between them. We also describe a global linear stability solver for FSI systems. Whereas global stability techniques are frequently used to deduce instability-driving mechanisms in fluid flows involving rigid stationary bodies, their use in FSI systems is less pervasive due to the challenges in addressing the multi-physics nature of these systems. Our global stability solver accounts for the fluid, the structure, and the coupling between them, and can therefore be used to understand physical mechanisms of the fully-coupled system. Finally, we use these numerical methods to study flapping-flag FSI systems that are promising candidates for flow energy harvesting. Compared with the conventional flag system in which the flag is placed in an unconfined flow and pinned or clamped at its leading edge, systems where the flag is either confined or where the boundary condition is placed on the trailing edge can exhibit larger flapping amplitudes and therefore generate more power. We explore the dynamics and energy conversion in these devices using the aforementioned numerical techniques.

Simulation of Gear-excited Vibrations in Wind Turbine Drivetrains with a Hybrid Numerical-Analytical Approach

Thomas Graetsch*, Frank Ihlenburg**, Marc Zarnekow***

*Hamburg University of Applied Sciences, **Hamburg University of Applied Sciences, ***Hamburg University of Applied Sciences

ABSTRACT

Gear vibrations due to varying mesh stiffness are a major source of tonal noise radiated from wind turbines. We present a hybrid approach for gear modeling that combines a detailed finite element analysis of meshing configurations with analytical models for the transient dynamics of helical gears. In a first step, the angle-dependent mesh stiffness of the gears is obtained from a sequence of static FE analyses that cover a complete meshing cycle. A comparison with results from the literature shows excellent agreement for spur gears. We also present numerical results for helical gears which so far have not been extensively studied. The results from the FE analyses are then used in the second step of the hybrid approach, where the transient dynamics of the gear system are simulated using two different analytical models. The first model describes the gears as rigid bodies with two rotational degrees of freedom. The bodies are connected via a linear spring-damper. An ordinary differential equation (ODE) of second order is obtained for the calculation of the commonly used Transmission Error (TE). The second model includes also the radial displacement along the line-of-action of the gears, which in turn can be used for the calculation of the dynamic bearing forces. The analytical models are solved numerically with a Runge-Kutta scheme. The frequency spectra of the dynamic gear vibration are obtained from the transient simulation by standard FFT. The hybrid approach was applied to the analysis of a wind turbine gearbox. The calculated TE frequency spectrum is in sound qualitative agreement with frequency response graphs of noise radiation, as obtained from acoustic field measurements. Over an analysis spectrum of several KHz, the peak frequencies in both spectra are matching exactly, while the deviation in peak amplitude characteristics is less than 5%. It can be concluded that the hybrid approach predicts well the gear vibration excitation of drivetrains, both for spur and helical gear configurations. We will also present numerical results for submodels of the drivetrain that are obtained by integrating the simulation of parameter-excited gear box vibrations into the vibroacoustic FE analysis of several drivetrain components. As the hybrid excitation model shall be used ultimatively in large-scale computational analyses of complete drivetrains, reduction methods are employed that shall allow the FE analysis of large models in reasonable runtime.

Structural Dynamics and Design with Polymorphic Uncertain Data

Wolfgang Graf*

*TU Dresden

ABSTRACT

The analysis and design of structures is one of the major tasks for structural engineers [1]. The objectives of numerical analysis and design, computing robust and reliable structures, can be realized by means of analyzing different variants, application of optimization tasks, or solving inverse problems. The method of choice depends on the aim of design and the problem. But common for all is that the uncertainty of the input parameters (design parameters and other parameters) has to be taken into account, in order to investigate a realistic computational model. Numerical structural design should be robust with respect to the polymorphic nature and characteristic of the available information. Uncertainties are inherently present in resistance of structural materials, environmental and man-imposed loads, boundary conditions, physical and numerical models, and to other types of intrinsic and epistemic uncertainties. Generally, the availability of information in engineering practice is limited. Incomplete, fragmentary, diffuse, and frequently expert specified knowledge leads to imprecision in data [2]. In addition, engineers have to cope with the objective variability and fluctuations in material, geometry and loading. This contribution presents approaches for design tasks analysed with optimization or solving the inverse problem. The advantages and disadvantages of each concept are pointed out. The solution of the inverse problem, suitable in early design stages to detect permissible design spaces is one of the main points of this contribution [3]. Especially for early design stages it´s necessary to take polymorphic uncertainty into account due to a lack in information. This incorporation yields to increasing numerical effort. One possibility to solve the design task in appropriate time is to apply surrogate models. This surrogate model generates a meta-model to reproduce the deterministic objective function. In this contribution, the improvement in efficiency is demonstrated by the sophisticated meta-model, Extreme Learning Machine. The applicability of the different approaches is demonstrated by means of engineering examples. References [1] Beck, J.; Graf, W.; Soize, C. A Multiscale Model to Analyze the Cost of Force Production in Skeletal Muscle Tissue

Jorge Grasa*, Silvia Blemker**

*Universidad de Zaragoza, **University of Virginia

ABSTRACT

The estimation of the total energy (thermal plus mechanical) liberated during a determined activity would be useful for a more complete understanding of the energetics of human movement [1]. In this work, a new multi-scale model is proposed to evaluate the energy release rate of skeletal muscle tissue in 3D models during active contractions. This model is based on the finite element method where the cross-bridge dynamics and the total rate of energy production is considered in the material constitutive law. The shortening/lengthening velocity of the sliding filaments allows determining the liberation of heat using a classic approximation [2]. The formulation was implemented into a hyperelastic transversally isotropic constitutive model as a user dynamic library in FEBio software [3]. The computational model predicts the heat liberation rate of the tissue and other mechanical variables such as stresses and strains under different active contraction conditions. Considering this novel approach, concepts like cost of force production and efficiency can be analysed in the model not only for the global tissue but also for different specific regions. The results provided by the model have been validated according to different outcomes obtained from the literature [4] that involve in vitro experimental tests of muscles subjected to different imposed strain and stimulation patterns. The computational tool developed can provide more insights into the form and function of muscles that could help for improving clinical treatments in related diseases. References 1. B. R. Key words: LPV modeling, indoor robot localization, audio, sewage system.

Abstract. The objective of the design of novel simplified acoustic model is to use it in order to locate autonomous robots in industrial environments. The acoustics of an industrial space is characterized by a non-linear dynamic. So far, in this kind of applications and for the sake of simplicity all the models are linear and this fact does not allow a suitable and accurate use. To consider all the information of the room and an improvement in the robot location a linear acoustic model with uncertainty is proposed in this research. The new contributed model is obtained by the convergence of existing methods, that is, between statistical models and the classical (and complex) wave model. Audio analysis requires the treatment of a huge amount of data which, obviously, cannot be achieved for real-time purposes. Therefore, the working range of frequencies are around Schroeder frequencies and a limited number of modes is selected using a suitable filter. This innovative model has been validated with real data through significant experiments in different rooms with an autonomous robot.

1. INTRODUCTION

Indoor robot localization is an important issue in the field of robotics. So far, usually for this purpose overall odometer, camera, infrared sensor, ultra sonic sensor, mechanical wave and laser are mainly used. Nowadays the role of acoustic perception in autonomous robots, intelligent buildings and industrial environments is increasingly important and in the literature there are different works[1,2].

It is very interesting the use of audio sensors according on the application. In industrial, man-made environments this type of sensors offers its main advantages: they are cheaper than other type of sensors, they hold a reach greater than the ultrasound sensors and they can cover a large area of exploration (with low directivity), they are not sensitive in front of changing light conditions, like cameras. Although audio sensors present low resolution to detect obstacles this fact is not too much relevant in industrial environments.

In an industrial plant to establish the transmission characteristics of a sound between a stationary audio source and a microphone in closed environment there are different study models: 1) the beam theory applied to the propagation of the direct audio waves and reflected audio waves in the room; 2) the development of a lumped parameters model similar to the model used to explain the propagation of the electromagnetic waves in the transmission lines and the study of the solutions given by the wave equation[11]. Other authors propose a transfer function of a

room, denoted RTF (Room Transfer Function) that carries out to industrial plant applied sound model[3, 9, 10]. In these works, the complexity to achieve the RFTs is evident as well as the need of a high number of parameters to model the complete acoustic response for a specific frequency range, even with almost ideal conditions.

In reference[13] authors presented a first approximation to a theoretical model set-up which modeled the RTF in an industrial plant in order to locate mobile robots in such environments. In the present work, this model will be studied in depth as well as the features in the proposed RTF that are more suitable to be used by a mobile robot to navigate in an industrial plant; we have simplified the methodology and our goal is to determinate the x-y coordinates of the robot. In such a case, the obtained RFT will not present a complete acoustic response, but will be powerful enough to determine the robot's position.

The acoustic response of an industrial plant depends mainly on its dimensions, but also on the different absorption coefficients of the materials that form the walls, the floor and the ceiling of the plant. This work is focused in the audio waves that are generated by rotary engines present in industrial environments. Those engines generate typically a reverberant field due to the successive reflections of the waves with the environment bounds. In order to simplify the establishment of a theoretical model as well as the obtaining of the experimental model by identification, a filtering step is introduced. In this phase, the most important harmonic component in the emitted signal spectrum will be selected.

In authors' previous works[7, 8, 12] the navigation system was presented. Those works investigated the feasibility of using sound features in the space domain for robot localization (in x-y plane) as well as robot's orientation detection. A robust sound-based indoor robot's pose (x, y, θ) detection system was proposed utilizing two microphones. For this reason, in this present work the navigation system will be skipped and the work will be focused in obtaining a more general model for rooms/closed environments through audio features. This model is LPV (linear parameters varying)[14] because the parameters of the model vary along the robot's navigation. Besides, this is a simplified model with the objective to obtain a low computational time in the robot self-localization process. The calibration of these parameters is carried out by physical equations and experimentation altogether. This new model is validated through significant experiments in a real and hazardous environment with a real robot: the sewage system in Barcelona city.

2. SOUND MODEL IN A CLOSED ROOM

2.1. Theoretical model

The acoustical response of a closed room (with rectangular shape), where the dependence with the pressure in a point respect to the defined (*x*,*y*,*z*) position is represented by the following wave equation:

$$Lx\frac{\partial^2 p}{\partial x^2} + Ly\frac{\partial^2 p}{\partial y^2} + Lz\frac{\partial^2 p}{\partial z^2} + k^2 p = 0 \qquad (1)$$

Lx, Ly and *Lz* denote the dimensions of the length, width and height of the room with ideally rigid walls where the waves are reflected without loss, Eq. (1) is rewritten[6] as:

$$p(x,y,z) = p_1(x)\,p_2(y)\,p_3(z) \tag{2}$$

when the evolution of the pressure according to the time is not taken into account.

Then (2) is replaced in (1), and three differential equations can be derived and it is the same for the boundary condition. For example, p_1 must satisfy the equation:

$$\frac{d^2 p_1}{dx^2} + k_x^2 p_1 = 0 \tag{3}$$

with boundary conditions in $x = 0$ and $x = Lx$:

$$\frac{dp_1}{dx} = 0$$

k_x, k_y and k_z constants are related by the following expression:

$$k_x^2 + k_y^2 + k_z^2 = k^2 \tag{4}$$

Equation (3) has as general solution:

$$p_1(x) = A_1 \cos(k_x x) + B_1 \sin(k_x x) \tag{5}$$

Through (3) and limiting this solution to the boundary conditions, constants in (5) take the following values:

$$k_x = \frac{n_x \pi}{L_x};\; k_y = \frac{n_y \pi}{L_y} \;\; and \;\; k_z = \frac{n_z \pi}{L_z}$$

being n_x, n_y and n_z positive integers. Replacing these values in (5) the wave equation eigenvalues are obtained:

$$k_{n_x n_y n_z} = \pi \left[\left(\frac{n_x}{L_x} \right)^2 + \left(\frac{n_y}{L_y} \right)^2 + \left(\frac{n_z}{L_z} \right)^2 \right]^{1/2} \tag{6}$$

The eigenfunctions or normal modes associated with these eigenvalues are expressed by:

$$p_{n_x n_y n_z}(x,y,z) = C_1 . \cos\left(\frac{n_x \pi x}{L_x} \right) . \cos\left(\frac{n_y \pi y}{L_y} \right) . \cos\left(\frac{n_z \pi z}{L_z} \right) . e^{j\omega t}$$

$$e^{jwt} = \cos(wt) - j \sin(wt) \tag{7}$$

being C_1 an arbitrary constant and introducing the variation of pressure in function of the time by the factor $e^{j\omega t}$. This expression represents a three dimensional stationary waves space in the room. For the eigenfrequencies corresponding to (6), the eigenvalues can be expressed by:

$$f_{n_x n_y n_z} = \frac{c}{2\pi} k_{n_x n_y n_z}, \; f_{n_x n_y n_z} = \sqrt{f_{nx}^{\;2} + f_{ny}^{\;2} + f_{nz}^{\;2}} \;\; \text{and}$$

$$f_{n_x n_y n_z} = \sqrt{\left(\frac{n_x c}{2L_x} \right)^2 + \left(\frac{n_y c}{2L_y} \right)^2 + \left(\frac{n_z c}{2L_z} \right)^2}, \tag{8}$$

where c is the sound speed. Therefore, the acoustic response of any close room presents resonance frequencies (eigenfrequencies) where the response of a sound source emitted in the room

at these frequencies is maximum. The eigenfrequencies depend on the geometry of the room and also depend on the materials reflection coefficients, among other factors.

In our case, the transform function f_T (that relates the distance between feature space coefficients of each signal vs. source signal (see ref[13]) with the distance between the points (x,y) in the space domain) is represented by (7), considering that the pressure is the square of the amplitude of sound signals (S_j) for an specific time. The solution of this equation is real because imaginary numbers are neglected, and represented as:

$$S_j(x,y) = C_2.\cos\left(\frac{n_{d_{xy}}\pi d_{xy}}{L_{d_{xy}}}\right) \tag{9}$$

where C_2 is an arbitrary constant.

The corresponding resonant frequencies that are obtained are indicated in Table 1. Specifically, in this Table the resonant frequency corresponding to the propagation mode (3, 0, 2) can be observed. This frequency is close to 100Hz that is selected from the signal spectrum when the climatic chamber is used as sound source.

Table 1. Resonant frequencies in the experiment.

n_x	n_y	n_z	f_{nx}	f_{ny}	f_{nz}	f(Hz)
3	2	1	49,1	68,3	43,1	94,54
4	2	0	65,5	68,3	0,0	94,62
2	1	2	32,7	34,2	86,3	98,37
3	0	2	49,1	0,0	86,3	99,25
0	3	0	0,0	102,5	0,0	102,48
1	3	0	16,4	102,5	0,0	103,77
4	2	1	65,5	68,3	43,1	103,98

For mode (3, 0, 2), this equation indicates the acoustic pressure in the rooms depending on the x-y robot's position, and this is:

$$p_{n_x n_y n_z}(x,y) = C_1.\cos\left(\frac{3\pi x}{10{,}54}\right).\cos\left(\frac{1{,}4\pi}{4}\right) \tag{10}$$

With these ideal conditions, for an ideal value for constant C_1 = 2 and for an ideal room without audio losses, the theoretic acoustic response in the rooms for this absolute value of pressure, and for this propagation mode.

2.2. Transfer function

Since the dimensions of industrial plants will be comparable to the wavelength of audio signals presents in the environment, distributed constant models can be used in order to model the audio waves propagation, in a similar way to those proposed for electromagnetic signals transmission lines.

In ref[4] a model based in the sum of second order transfer functions is proposed; these functions have been build between a sound source located in a position ds emitting an audio signal

with a specific acoustic pressure P_s and a microphone located in dm which receives a signal of pressure P_m with a time delay t_{rm}; each function represents the system response in front to a propagation mode.

The first contribution of this work is to introduce an initial variation to this model considering that the sound source has a fixed location, and then this model can be expressed as:

$$\frac{P_m(s)}{P_s(s)} = \sum_{n=1}^{M} \frac{K_m s e^{t_{rm} s}}{s^2 + 2\xi_n \omega_n s + \omega_n^2} \tag{11}$$

Because our objective is not to obtain a complete model of the acoustic response of the industrial plant, it will not be necessary to consider all the propagation modes in the room and we will try to simplify the problem for this specific application without the need to work with models of higher order.

To implement this experiment, the first step is to select the frequency of interest by a previous analysis of the audio signal frequency spectrum emitted by the considered sound source (an industrial machine). Those frequencies components with a significant acoustic power will be considered with the only requirement that they are close to one of the resonant frequencies of the environment. The way to select those frequencies will be through a band-pass digital filter centered in the frequency of interest. Right now, the term M in the sum of our model will have the value N, being this new value the propagation modes resulting from the filtering process.

3. PROPOSED LPV MODEL IN A CLOSED ENVIRONMENT

For a concrete propagation mode, the variation that a stationary audio signal receives at different robot's position can be modeled, this signal can be smoothed by the variation of the absorption coefficient of the different materials that conform the objects in the room; those parameters are named K_{nm} and ξ_{nm} , and (12) results:

$$H(s, d_m) = \frac{P_m(d_m, s)}{P_s(s)} = \sum_{n=1}^{N} \frac{K_{nm}(d_m) s e^{t_{rm} s}}{s^2 + 2\xi_{nm}(d_m)\omega_n(d_m) s + \omega_n^2(d_m)} \tag{12}$$

where the subscript n indicates the natural frequency associated to the considered propagation mode (ω_n) and the subscript m indicates the distance of the microphone to the sound source (d_m). This natural frequency (ω_n) of the transfer function room depends on the room characteristics: L_x, L_y and L_z resulting in an LPV indoor model.

The distance (d_m) from the robot to the sound source is given by the expression:

$$d_m = \sqrt{(x_r - x_s)^2 + (y_r - y_s)^2 + (z_r - z_s)^2} \tag{13}$$

where (x_r,y_r,,z_r) are the robot location coordinates and (x_s,y_s,z_s) are the sound source coordinates.

Using (12) the module of the closed room in a specific transmission mode ω_n is:

$$\left|H(j\omega_{nm}, d_m)\right| = \frac{K_{nm}}{2\xi_{nm}\omega_n} \tag{14}$$

Assuming that the audio source only emits a frequency ω_1 with an amplitude P_s the room response in the propagation mode ω_n for a specific coordinate (x,y,z) of the room is:

$$|H| = \left|\frac{P_m}{P_s}\right|_{n_x,n_y,n_z} = \left|C_1 \cos\left(\frac{n_x \pi x}{L_x}\right)\cos\left(\frac{n_y \pi y}{L_y}\right)\cos\left(\frac{n_z \pi z}{L_z}\right)\right| \quad (15)$$

being z the height of the microphone from the floor, and with

$$f_n = \sqrt{f_x^{\,2} + f_y^{\,2} + f_z^{\,2}} \text{ and } \omega_n = 2\pi f_n .$$

For instance, if a one-dimensional environment is considered where the three modes are propagated, as it can be seen in Fig. 1, and the observer is located at a distance d_m = 2 m, the values of maximum pressure in this point are A_1, A_2 and A_3. The total pressure received in this point is the sum of the partial pressures given by each mode.

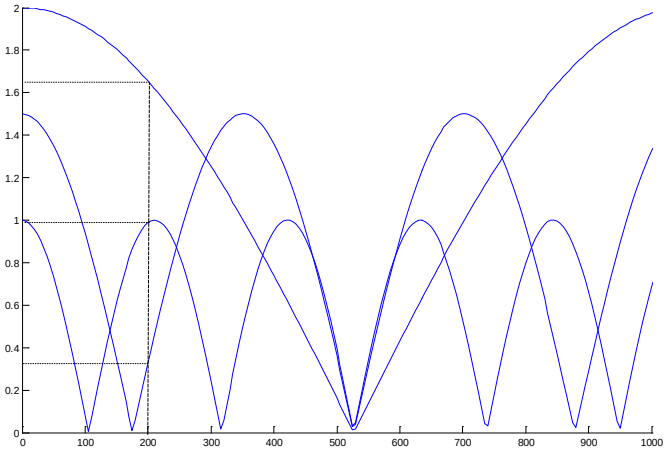

Figure. 1. Response in the one-dimensional case.

For a specific mode and location, the system behaves as a pass band filter, presenting a maximum response at the resonant frequency for the considered mode and a lower response when the signal frequency moves away from the resonant frequency.

Taking into account these considerations, equaling (14) and (15), it results:

$$\xi_{nm} = \frac{K_{nm}}{2\omega_n C_1 \left|\cos\left(\frac{n_x \pi x}{L_x}\right)\cos\left(\frac{n_y \pi y}{L_y}\right)\cos\left(\frac{n_y \pi z}{L_z}\right)\right|} \quad (16)$$

If the filter is non ideal then more than one transmission mode could be considered and therefore the following expression is obtained for a robot position d_m and a resonant frequency ω_n given by the propagation mode n_x,n_y *and* n_z :

$$\sum_{l=1}^{n} \frac{K_{nm}}{2\xi_{nm}\omega_n} = \sum_{l=1}^{n} C_1 \left|\cos\left(\frac{n_x \pi x}{L_x}\right)\cos\left(\frac{n_y \pi y}{L_y}\right)\cos\left(\frac{n_z \pi z}{L_z}\right)\right| \quad (17)$$

If the emitted signal power by the sound sources is constant and the audio signal power acquired with the microphones varies along the robot's position, then the pole positions in the s plane,

for the considered propagation mode, will vary in the different robot's positions and their values will be:

$$s_{1nm} = -\xi_{nm}\omega_n + \omega_n\sqrt{1-(\xi_{nm})^2} \tag{18}$$

$$s_{2nm} = -\xi_{nm}\omega_n - \omega_n\sqrt{1-(\xi_{nm})^2} \tag{19}$$

This is an LPV grey-box model where the damping factor and the natural frequency can be determined by theoretical laws and the parameter K_{nm} is calibrated through experimentation.

4. EXPERIMENTAL RESULTS

Authors have been tested an autonomous mobile robot in a very hazardous environment: the sewage system in Barcelona city.

The methodology applied to determine the robot's position is the following:

1) Initially a real source of sound is located in the environment. In this case an electrical is used, generating a real sound with many frequencies with its spectrum.
2) The robot acquires an audio signal in its current position and performs a LPV modeling process taking as input signal the filtered sound source signal and as output signal the acquired and filtered signal. The parameters corresponding to the obtained poles in this identification process will be the features components for further steps.
3) The Euclidean distances in the feature space are calculated between the current position and the different labeled samples.
4) The two first samples are chosen and the distance between them and the robot's position are then calculated. Through a transformation function f_T (see ref[13]) the distance in the feature domain is converted to a distance in the space domain. These two distances in the space domain give two possible positions by the crossing circles of distances.
5) To discriminate between both possible solutions, the angle between each one and the platform containing the microphone array (which contains a compass) are calculated, and the closest one to the platform angle will be chosen as discriminatory variable to select the current robot's position.
6) Steps 4 and 5 are repeated with the remaining labeled samples, and the solution is chosen among the closest angle to the robot's platform.

For an accurate explanation of the algorithm, the microphone array and the robot used in the experiments see ref[13].

The acoustic response of the environment is very directional, and this fact leads to consider some uncertainty in the determination of the transformation function which relates the distance in the feature space and the domain space.

The robot, in order to determine its location, will perform the identification process between the emitted sound signal by the sound sources and the acquired signal by the microphone. Furthermore, the robot incorporates a rotary platform allowing orientating the microphone to the audio source, determining this orientation angle accurately.

As it can be seen in Fig. 2, the robot follows the trajectory indicated by the arrows. In the figure is shown the airborne picture of the city, showing the path followed by the robot beneath the street, that is, in the sewers. There are two kind of audio samples: learning and recognition samples. For the collection of learning samples, a set of audio samples have been acquired along the path with known position, authors have measured which is the exact position of such samples, that is, knowing the ground truth. Because many of these samples have been collected they are not shown in the map. In the other hand, the recognition samples are those that once collected the robot has to calculate its position based on the above system and with the information given by the previous samples in the learning phase. Those samples are labelled as P1...P8.

Figure 4 shows the hazardous environment that robots finds in the sewers, and the operative to enter the robot to the sewage by a manhole.

The acquired signal in the sewer will be used in the identification process, See Fig. 5. This signal is time-continuous and, initially, non-stationary; but because the signal is generated by revolving electrical machines it has some degree of stationarity when a high number of samples is used, in this case, 50,000 samples (1.13 seconds). The fundamental frequency is located at 100Hz, and there are also some significant harmonics above and below it. In the filtering step, in order to simplify the identification process only the fundamental frequency at 100Hz and its closer harmonics will be taken into account, specifically those corresponding to the frequencies 178, 147.6, 89 and 66.8 Hz, that get involved due to the non-ideality of the implemented filter.

The sampling frequency is 44,100Hz. Other lower frequencies could be used instead, avoiding working with a high number of samples, but this frequency has been chosen because in a near future a voice recognition system will be implemented aboard the robot and it will be shared with this audio localization system. To facilitate the plant identification process centering its response in the 100Hz component, the input and output signals will be filtered and, consequently, the input-output relationship in linear systems is an ARX model.

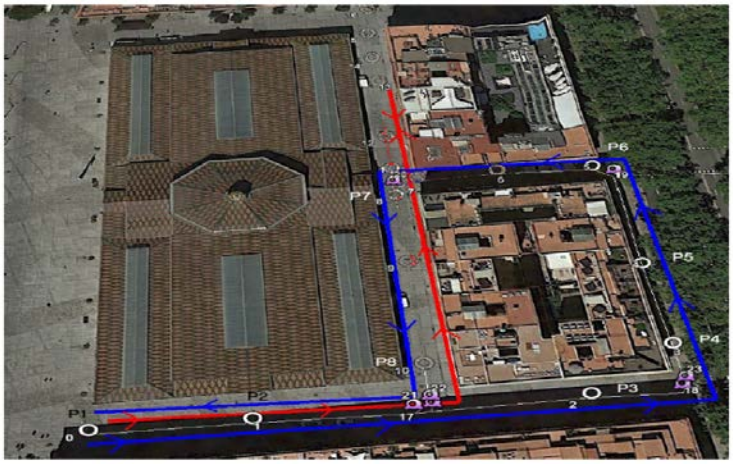

Figure 3. Robot environment: path followed by the robot. In red: test path; in blue path: real path with labels P1...P8 where recognition samples are collected.

Figure 4. View seen from the robot in the sewers, and some workers lowering the robot by a manhole.

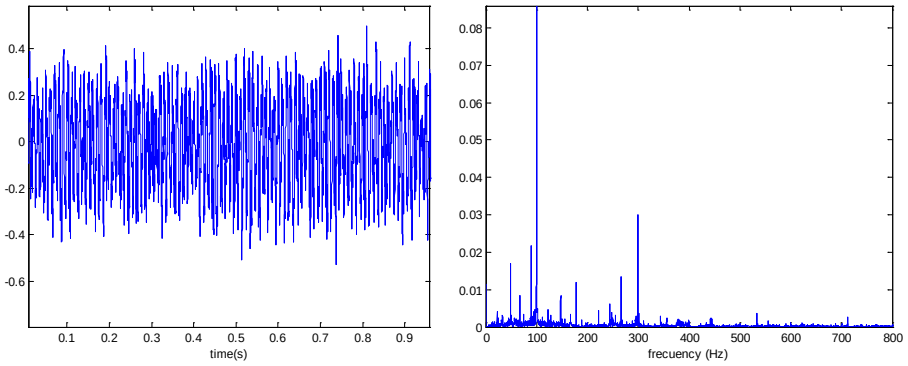

Figure 5. Source signal and its frequency spectrum.

To do that, a band-pass filter is applied to the acquired sound signals by the robot, specifically a 6th-order digital Cauer filter. Fig. 6 shows the results of the filter for the input signal in, for instance, robot position R_4 in the climatic chamber.

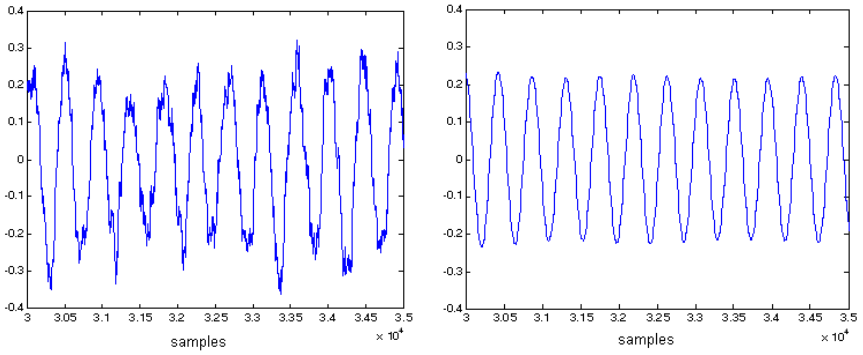

Figure 6. P3 sound signal (left) and its filtered signal (right).

The propagation modes closer to the frequency of 100Hz and its harmonics considered in the filtering process are indicated in Table 2.

Table 2. Considered propagation modes.

n_x	n_y	n_z	f_{nx}	f_{ny}	f_{nz}	f(Hz)
4	0	0	65,5	0,0	0,0	65,46
1	0	2	16,4	0,0	86,3	87,79
3	0	2	49,1	0,0	86,3	99,25
1	2	3	16,4	68,3	129,4	147,22
2	1	4	32,7	34,2	172,5	178,87

From the proposed theoretical model, the damping coefficient for these frequencies is function of gain *K* and the considered robot's position (x,y,z).

$$\xi_{nm} = \frac{K_{nm}}{2\omega_n C_1 \left| \cos\left(\frac{n_x \pi x}{L_x}\right) \cos\left(\frac{n_y \pi y}{L_y}\right) \cos\left(\frac{n_y \pi z}{L_z}\right) \right|} \tag{20}$$

In this model the acoustic energy dissipation has not been modeled and it is considered by gain K in the model and the constant C1 that appears in the wave equation (with a value of 2, as it has been aforementioned) for a signal frequency considered in a specific robot's position. The acoustic energy is degraded into thermal energy due to the losses in reflection that will depend on the materials mainly. It is important to consider that the presence of obstacles will introduce a new loss factor that will depend on the position and size of the obstacle and the material that form it. The following expression can be used to model those effects:

$$\frac{K_{nm}}{C_1} = K_2 e^{-mf} \tag{21}$$

Then (20) can be written as follows

$$\xi_{nm} = \frac{K_2 e^{-mf}}{2\omega_n \left| \cos\left(\frac{n_x \pi x}{L_x}\right) \cos\left(\frac{n_y \pi y}{L_y}\right) \cos\left(\frac{n_y \pi z}{L_z}\right) \right|} \tag{22}$$

indicating that the higher the frequency the higher the damping ratio. From the experimental measurements in the plant, the parameters K_2 and m can be determined in (21) which quantify the different losses in the acoustic signals considered in the environment. Good results are obtained for $K_2 = 50$ and m = 0.015, resulting

$$\frac{K_{nm}}{C_1} = 50 e^{-0.015 f} \tag{23}$$

The LPV model is obtained from the theoretical laws and the experimental data acquired in labeled samples. The damping factor and the natural frequency are obtained by the expressions explained in the Section 3 and the previous equations (21)-(23). The amplitude constant K_{nm} is calibrated by experimentation through the least square method[4]. This procedure is carried out for those 5 models. They have been validated with the error criteria of FPE (Function Prediction Error) and MSE (Mean Square Error), yielding values about 10e-10 and 3% respectively using 3000 for this validation. Besides, for the whole estimated models the residuals autocorrelation

and cross-correlation between the inputs and residuals are uncorrelated, indicating the goodness of the models.

Table 3. Results of experiments.

Robot's position	Abs. Error X(%)	Abs. Error Y(%)
P1	1.24	0.34
P2	3.43	2.54
P3	2.04	1.23
P4	0.45	1.98
P5	3.54	3.06
P6	5.43	6.96
P7	6.43	6.12
P8	2.34	0.89

There exists another uncertainty of about ± 7.5 degrees in the angle determination due to the rotary platform in the robot that contains the microphones. Finally, to determine the current robot's position the solution that provides the closest angle to the robot's platform will be chosen. The results of our experiments are shown in Table 3. The robot made the same path up to 10 times, and the samples P1...P8 have been acquired at every run. The result is the average error for the 10 runs. The average error in absolute value for the X axis is 3.11% and in the Y axis is 2.89% providing estimated x-y positions good enough and robust.

5. CONCLUSIONS

In this article a new simplified LPV theoretical model has been presented which corresponds to the acoustic response. The aim of the model is to locate mobile robots in such environments. In this work authors presented a methodology to be applied in order to simplify the identification process in industrial plants using the acoustic signals generated by typical engines in those environments.

Because the model will be used by a mobile robot to navigate in an industrial plant, the methodology has been simplified and the goal is to determinate the x-y coordinates of the robot. In such a case, the obtained RFT will not present a complete acoustic response, but it has been demonstrated that the results are very good. The obtained feature space is related with the space domain through a general approach with acoustical meaning. The validation of this novel approach is tested in a real environment, in this case a section of a sewage system obtaining promising results. The results keep being very good when the uncertainty is incorporated in the transformation function.

Residual-Based Variational Multiscale Simulation of Sediment Transport With Morphological Changes

Malú Grave*, José Jerônimo Camata**, Alvaro Coutinho***

*Federal University of Rio de Janeiro, **DCC/UFJF, ***Federal University of Rio de Janeiro

ABSTRACT

Sediment transport induced by fluid flows is a field of great importance in engineering applications because there are a lot of projects strongly affected by moving sediments. The transport of sediments in fluids encompasses the suspended load, where turbulence carries the sediment particles, and the bedload, where the particles near the bottom are moved sliding, rolling or by saltation, because of the shear stress on this region. The bed load transport implies bed morphological changes which are also induced by the erosion as a consequence of sediment entrainment into suspension. In this work, we implement all these phenomena as numerical models in libMesh, an open finite element library that provides a framework for multiphysics. Here, the mathematical model results from the incompressible Navier-Stokes equations combined with an advection-diffusion transport equation for suspended sediments. The Navier-Stokes equations are treated with the residual-based variational multiscale finite element formulation while the advection-diffusion transport equation uses a stabilized method with discontinuity capturing. Empirical models are used to represent the entrainment and the bedload transport rate of sediments. Special boundary conditions at the bottom are introduced to take into account sediments entrainment, as well as deposition. After each time step, we update the mesh according to the morphological changes at the bottom due the bed load transport and erosion, and an avalanching mechanism is applied in a way to avoid elevations higher than the sediment angle of repose. We validate the suspended load transport model and the boundary conditions simulating two well-documented test cases where experimental data are available. After that, we employ the full model, including bedload transport, in another test case, and the results obtained from our model are promising. Both flow field and scour pattern are similar to available experimental data.

A Class of Polygonal Spectral Elements with Adaptive p-Refinement for the Efficient Simulation of Wave Propagation Problems

Hauke Gravenkamp*

*University of Duisburg-Essen

ABSTRACT

This contribution presents a novel approach to constructing polynomial shape functions of arbitrary order on triangles and star-convex polygons. Each element is defined in local scaled boundary coordinates with the origin positioned within the kernel of the polygonal domain. Two independent sets of one-dimensional shape functions are defined along both local coordinates, i.e., the circumferential and radial direction, respectively. The two-dimensional shape functions are constructed as the tensor product of the one-dimensional polynomials similar to conventional spectral elements. This procedure allows choosing the element order independently not only for each edge but also along the radial direction. Consequently, highly flexible local refinement schemes can be applied where this element type enables the straightforward transition between subdomains subject to different meshing requirements or an elevation of the element order in the vicinity of stress concentrations. In particular, this approach is beneficial for the simulation of wave propagation phenomena, where the required nodal density is mainly predetermined by the local wavelength at the frequency of interest, rather than the geometrical complexity. The proposed polygonal element exhibits all advantages of conventional (quadrilateral) spectral elements, namely high-order completeness, partition of unity, the 'Kronecker-delta-property', as well as a straightforward construction of shape functions. In addition to the advantages that come with the extension to polygonal discretizations, computational costs for the integration of the coefficient matrices are reduced since the proposed shape functions can be integrated along both local coordinates separately, hence requiring only one-dimensional quadrature rules. Despite the fact that these elements allow local p-refinement in a highly flexible manner, the mass matrix can be lumped without loss of accuracy - two features which are usually considered to be mutually exclusive.

An Efficient Blended Mixed B-spline Formulation for Non-polar Thin Structural Models

Leopoldo Greco*, Massimo Cuomo**, Loredana Contrafatto***, Salvatore Gazzo****

*university of study of Catania, **university of study of Catania, ***university of study of Catania, ****Universitè de Lyon

ABSTRACT

Mixed formulations of the $\bar{B}$ type, when applied to B-spline representations, bear significant computational cost and lead to a full stiffness matrix. In this work we present an efficient mixed formulation for avoiding membrane locking of curved non-polar thin structural models, i.e. plane Kirchhoff rod and Kirchhoff-Love shell models, in the context of isogeometric analysis. An efficient spline reconstruction of the assumed axial strains obtained by means of a local projection at the element level is performed using the method proposed by Thomas et al. in [1] for the reconstruction of the geometry. In this way a much smaller bandwidth of the stiffness matrix is obtained with respect to the non local $\bar{B}$-formulation, with significant reduction of the computational cost. The blended mixed formulation splits in two steps: in the first step the local $\bar{B}$ operators are defined at the element level via projection of the strain measure (both L2- projection and discrete collocation approaches are considered). Successively, by means of the spline reconstruction algorithm, the global projection of the strain measures at the patch level is defined. Numerical experiments show that the proposed method, in addition to completely remove membrane locking, yields the same accuracy and rate of convergence as the non local $\bar{B}$-method.

Analysis of Forces through the Seated Pelvis during Under Body Blasts

Preston Greenhalgh*, Matthew Panzer**, Edward Spratley***, Robert Salzar****

*University of Virginia, **University of Virginia, ***University of Virginia, ****University of Virginia

ABSTRACT

Injury mitigation techniques for mounted soldiers, such as seat padding and mounting, have been implemented in mine-resistant ambush protected (MRAP) vehicles, but numerous pelvic injuries still occur within these vehicles during under body blast (UBB) events. To better prevent pelvic injuries during UBB events, a better understanding of how force is transmitted into the pelvis at very high load rates is imperative. To that end, a biofidelic finite element (FE) model of the pelvis can be a powerful tool to explore UBB response because of its low cost and ease of use in comparison to expensive and difficult high-energy cadaveric tests. Fourteen (14) bilateral gluteal soft tissue specimens were tested in axial compression using a custom drop tower. Each specimen included gluteal muscle, adipose tissue, and skin. The specimens were laid flat on a substrate attached to a load cell. A 22.7kg weight was dropped onto the specimens at 10 m/s, while a linear potentiometer was used to measure displacement of the indenter. An inverse finite element (IFE) method was used to calculate the material properties of the tissue from the drop tower data. The time-displacement data from the test was prescribed to the FE indenter. The force output from the simulation was exported to a custom program that iteratively compared the force output from the FE model to that of the experimental load cell, and selected new material coefficients based on a quasi-linear viscoelastic (QLV) material model until the force responses converged. A component pelvis FE model was made by modifying the GHBMC automotive FE model, matching the boundary and input conditions of previous experimental pelvis tests performed at the University of Virginia. The pelvis was potted at S1 attached to a load cell, and a plate acting as the seat impacted the pelvis. The pelvis soft tissue material in the FE model was updated using the QLV constitutive model found in the high rate material tests. Forces and moments from the sacrum load cell in the FE model were compared to the experimental data with the original and updated soft tissue model. From preliminary analysis, greater than 30% of the applied seat platen force was transmitted through the soft tissue of the posterior pelvis, while 70% was transmitted through the skeleton. This soft tissue contribution changes the location of the seat platen center of percussion posteriorly, and may contribute significantly to the observed injury distributions seen in theater.

Cardiac Fluid-Structure Interaction by a Hyperelastic Immersed Boundary-Finite Element Method

Boyce Eugene Griffith*, Charles Edward Puelz**, Simone Rossi***, Margaret Anne Smith****

*UNC, **UNC, ***UNC, ****UNC

ABSTRACT

During each cardiac cycle, muscle contraction and relaxation drive the blood flow through the four chambers of the heart and to the vascular system. The heart chambers – the ventricles and the atria – are separated by valves that ensure a unidirectional flow, from the right to the left heart and from the left heart to the vascular system. As the main purpose of the heart is to pump blood to the vascular system, the characterization of the cardiac blood flow is important to understand the impact of blood flow in health and disease. For this reason we have built a fluid-structure interaction model of the heart, which includes the 4 heart chambers, the valves and the main vessels, To handle the large deformations and complex geometries of the beating heart, we use the immersed boundary method to simulate the fluid-structure interaction problem. In particular, the momentum equation is solved "in a box" using the finite difference method, while the solid forces are computed on a finite element mesh. The heart muscle is assumed to be viscoelastic: the elastic stress is derived from an orthotropic strain-energy density function, while the viscous stress is inherited from the underlying Newtonian fluid. The contraction of the muscle is modeled by means of an active stress formulation driven by a simplified model for the intracellular Calcium transient. The active stress acts only in the fiber direction, which have been defined in the whole heart using simple Poisson interpolation methods. We'll discuss the construction of the whole heart model including the creation of the geometrical models, the generation of the fiber field in the 4 heart chambers and the hyperelastic immersed-boundary finite element method.

A Bayesian Encoder-Decoder Model Order Reduction Approach for Problems in Random Heterogeneous Media

Constantin Grigo*, Phaedon-Stelios Koutsourelakis**

*Technical University of Munich, **Technical University of Munich

ABSTRACT

The macroscopic behavior of random heterogeneous media is fully determined by its microstructural properties. However, due to computational complexity, it is often barely feasible to simulate problems directly on their microscale. Reduced order modeling (ROM) techniques aim at alleviating this computational burden by only retaining most relevant fine scale material properties. We develop a fully probabilistic (semi-)supervised learning approach based on only a few tens of forward model runs which maps high-dimensional random material microstructures onto a much lower dimensional latent space (encoding) using macroscopic feature information such as porosity, correlation length or interface conditions. These latent variables then serve as the input to a less accurate, though much cheaper reduced order model (potentially based on different constitutive behavior) which emulates the expensive fine scale problem. Finally, the ROM output is used to probabilistically reconstruct the fine-grained model response (decoding), leading to sharp predictive distributions centered around the true solution field. By making use of information-theoretic criteria, the model is capable to automatically adapt the ROM emulator complexity until a user-specified level of accuracy/efficiency is met. We apply the discussed method to different problems in random heterogeneous media and show possible applications in stochastic optimization-, inverse- or control problems.

Sample Generation of Vector-valued Gaussian Functions with Prescribed Accuracy

Mircea Grigoriu*

*Cornell University

ABSTRACT

The generation of samples of Gaussian random functions is based on approximate representations which depend on finite families of random variables and converge in some sense to target Gaussian functions, e.g., truncated Karhunen-Lo\`eve (KL) series. The theory of KL series is well-established but their properties for vector-valued random functions have not been examined systematically. The common selection of truncation levels based global errors results in representations whose components may have very different accuracies. To address this potential limitation, we propose the following two-step algorithm. First, truncation levels {m_i} are selected for the KL representations of the components {Z_i(x)} of a target vector-valued Gaussian function Z(x) such that they meet specified accuracies. This selection involves one dimensional processes. Second, the levels $\{m_i\}$ are accepted or increased if the accuracies of resulting cross correlation functions of Z(x) satisfy or violate preset constraints. The algorithm is based on the facts that (i) the products of eigenfunctions of the correlation functions of components of Z(x) provide an orthonormal basis for the cross correlation functions of Z(x) and (ii) the correlations of the random coefficients of KL representations result from projections of the cross correlation functions of Z(x) on the orthonormal bases obtained from the eigenfunctions of the correlation functions of {Z_i(x)}. Numerical examples are presented to illustrate the implementation of the proposed Monte Carlo algorithm and demonstrate its performance.

The Embedded Unit Cell (EUC): Nonlinear Material Response

Marina Grigorovitch*, Erez Gal**

*Department of Structural Eng., Ben-Gurion University of the Negev, **Department of Structural Eng., Ben-Gurion University of the Negev

ABSTRACT

In this research, the multiscale modeling ability of coupling between the macroscale structure and microscale material is extended by mean of the presented formulation that called “Embedded Unit Cell (EUC)”. The embedded unit cell (EUC) approach is a concept designed to facilitate homogenization and multi scale analysis of composite materials/domains in cases where the classical theory of homogenization is not valid due to lack of periodic microscopic response. The EUC approach is based on microscopic solution of unit cell restricted by non-periodic boundary conditions and continuum domain surrounding the unit cell in order to describe the mechanical relations between various scales. The proposed methodology relies on mathematical formulation, multi-scale analysis procedure and generalized theory of homogenization, and is intended to widen the applicability of the analysis to the zones, where classical formulation cannot be applied because the required periodicity assumption is not valid. Up to now, this method was challenged by solution of several types of problems. The linear response of homogenization problems at boundary zones, which are not periodic with the rest of the structure, was successfully evaluated by the developed EUC procedure by eventually reducing the model complexity and computing resources demand. Following that, the stress concentration problems were analyzed at both elastic and elastic-plastic type of response. Such problems are characterized by homogeneous structure and shape, with exception of small-size zones with local non-periodicity relating to the rest of the structure. These small domains represent stress concentration zones, which response is evaluated by complex FE models and characterized by very demanding computing resources. The non-linear problems with elastic-plastic type of response are difficult to be solved using classical homogenization methods, because periodic assumption is hardly valid. The pair of microscopic and macroscopic problems has to be solved more than once upon incremental loading and instantly changing equivalent material properties, in contrast with single solution in the case of the linear elastic problems. Sequential information passing between the scales has to be replaced by consecutive information passing, causing enormous effect on the complexity of the numerical algorithm, so that the implementation of the evaluation procedure has been involved with advanced reprogramming of complicated finite elements software. A numerical verification study shows that the suggested approach provides appropriate and accurate approximation, compared to the reference solutions of displacement field and micro-scale stress fields.

Fast Evaluation of the Distance to the Wall in Eulerian Fluid-Structure Interaction Computations

Sebastian Grimberg*, Charbel Farhat**

*Stanford University, **Stanford University

ABSTRACT

Highly nonlinear, turbulent, dynamic, Fluid-Structure Interaction (FSI) problems characterized by high Reynolds number flows, large structural displacements and deformations, as well as self-contact and topological changes are encountered in many applications including the study of supersonic parachute inflation dynamics [1]. For this class of FSI problems, the Eulerian computational framework, which often implies an Embedded (or immersed) Boundary Method (EBM) for CFD that is robust for viscous flows [2], is often the most appropriate one. In many circumstances, this framework requires the computation of the time-dependent distance to the wall — that is, the distance from each active mesh node of the embedding mesh to the nearest embedded discrete surface, which evolves in time and with the motion/deformation of this surface. Such circumstances include, for example, modeling turbulence using the Spalart-Allmaras or DES turbulence model, and performing Adaptive Mesh Refinement (AMR) in order to track the boundary layers. In the context of explicit-explicit fluid-structure time-integration schemes, which are often required to resolve the physics of the aforementioned class of FSI problems, evaluating at each time-step the distance to the wall is computationally prohibitive. For this reason, this talk presents two complementary approaches for reducing this computational cost. The first one recognizes that many quantities depending on the wall distance are relatively insensitive to its inaccurate evaluation in the far field. Therefore, it simplifies a state-of-the-art algorithm for computing the distance to the wall accordingly. The second approach relies on an effective distance error estimator to update the evaluation of the distance function only when otherwise a quantity of interest that depends on it would become tainted by an unacceptable level of error. The talk will also highlight the potential of combining both approaches for dramatically accelerating the solution of highly nonlinear, turbulent, FSI problems by reporting on the performance of the simulation of the inflation of a disk-gap-band parachute system in a supersonic airstream. 1. Coupling of Incompressible Fluid Features to Mechanical and Thermal Features of LSDYNA

Roger Grimes*, Facundo Del Pin**, Inaki Caldichoury***, Rodrigo Paz****

*Livermore Software Technology Corporation, **Livermore Software Technology, ***Livermore Software Technology, ****Livermore Software Techonology

ABSTRACT

LSDYNA has evolved from a Finite Element Package for Mechanical Simulation to a Multi-Physics Simulation Package. Initially that meant the inclusion of Thermal capabilities for the Mechanical Capabilities. But LSDYNA now has features for Electromagnetics, Incompressible Fluid Flow and Compressible Fluid Flow. Over a decade ago LSTC (Livermore Software Technology) started the development of Incompressible Fluid (ICFD) Flow Features which required integration with the existing mechanical and thermal capabilities. This talk will present how we implemented this coupling for - ICFD with Mechanical Explicit Time Integration - ICFD with Mechanical Implicit Time Integration - ICFD Conjugate Heat Transfer with Mechanical Thermal Computations We will highlight the coupling of features with examples.

Controlling the Solution Transfer Error in Multi-physics Coupling for Climate Problems

Iulian Grindeanu*, Vijay Mahadevan**, Robert Jacob***

*ANL, **ANL, ***ANL

ABSTRACT

It is well known that operator decomposition and unresolved solution of coupled atmosphere and ocean models, or physics and dynamics components of an atmosphere, can lead to large numerical approximation errors that can also cause stability issues. In this context, one of the components contributing to the spatiotemporal accuracy is due to the mapping between different discretizations of the sphere, to resolve spatial scales of interest in the various coupled model components. In some atmospheric and ocean model solvers, consistent and conservative remapping strategies strongly determine the propagation of discretization accuracy between models. This could also become an issue in atmosphere models where physics and dynamics are on different grids. Tracer advection done by remapping is also subject to these errors. Understanding and controlling all sources of errors in a coupled system dynamically will be key to achieving predictable and verifiable results on future architectures. We will compare several conservative and non-conservative solution transfer and remapping methods implemented within the framework of TempestRemap and MOAB in comparison to the state-of-the-art methods implemented within ESMF, and discuss the implications on numerical accuracy and computational efficiency for representative coupled model problems.

Computed Tomography Characterization of Voids in Ordinary and Ultra-High Performance Concrete

Andrew Groeneveld*, Charles Burchfield**

*US Army Engineer Research and Development Center, **US Army Engineer Research and Development Center

ABSTRACT

Ongoing research on multiscale modelling of concrete materials requires accurate characterization of the structure of the material at lower length scales. In order to characterize these materials at these scales, void sizes and spacing should be investigated along with matrix constituents and any aggregates or fibers present. This work investigates the volume and spacing of voids in two concretes, SAM-35 and Cor-Tuf Baseline. X-ray computed tomography was used to image the internal structure of concrete cylinders. Volume element (voxel) sizes in the reconstructed 3D images ranged from 32 to 57 µm. Voids were identified using an x-ray attenuation threshold and connected component analysis. The void volume and inter-void spacing (based on Delaunay triangulation between centroids) were determined. Distribution fitting was performed to generate probability density functions for use in modelling.

Protein Transport in Curved Lipid Bilayer Membranes: An Extended Saffman-Delbruck Approach Incorporating Hydrodynamics in Curved Fluid Interfaces

Ben Gross*, Paul Atzberger**, Misha Padidar***

*University California Santa Barbara, **University California Santa Barbara, ***University California Santa Barbara

ABSTRACT

We develop fluctuating hydrodynamics approaches to extend Saffman-Delbruck theory to capture the collective drift-diffusion dynamics of proteins within curved lipid bilayer membranes. Our approach is at the level of fluid interfaces having any curved radial manifold shape. We take into account the two dimensional hydrodynamics of the two curved leaflets of the bilayer coupled with the three dimensional hydrodynamics of the surrounding bulk fluid. Using analytic and computational approaches, we show how Gaussian curvature can significantly impact dissipation within the curved two dimensional membrane fluid to augment the collective drift-diffusion dynamics of protein inclusions. We further show for the self-assembly of protein clusters that these effects contribute significant kinetic contributions giving differences with widely used non-hydrodynamic theories. We also present general results on the collective drift-diffusion dynamics when heterogeneous curved structures are present in the membrane geometry showing how these local Gaussian curvature effects influence hydrodynamic coupling in some interesting ways.

Algorithms for the Simulation of Curvilinear and Axisymmetric Hydraulic Fractures with Lag

Benjamin Grossman-Ponemon*, Adrian Lew**

*Stanford University, **Stanford University

ABSTRACT

Hydraulically-driven fractures are ubiquitous in nature as magma-filled dykes around volcanos or water-filled cracks which drive the calving ice sheets in the arctic. They are best known by their commercial use in fracking treatments by the oil and natural gas industry, leading an energy boom in the United States and abroad. Deeper understanding of these processes drive the need for robust simulation of hydraulic fractures. However, simulation of the evolution of fluid-filled fractures is difficult due to the need to track changing crack geometry, advance the fluid inside the crack, and compute a functional over the singular stress fields around the crack tip to determine the crack path. The recently-developed technique of Universal Meshes (UM)[1] offers a solution to these problems. By snapping only nearby nodes of a background mesh to the crack, the geometry of the problem may be resolved exactly, and a suitable domain on which to solve for the evolution of the fluid is generated. From UM, an algorithm to simulate fluid-filled fractures with lag is developed. Examples in plane-strain and axisymmetry are considered. Application and Numerical Solution of 14-Moment Maximum-Entropy-Based Moment Closures for Descirbing Non-Equilibrium Gaseous Flows with Shocks

Clinton Groth*, Lucie Freret**

*University of Toronto, **University of Toronto

ABSTRACT

The development and application of novel 14-moment maximum-entropy-based moment closures are explored for prediction of non-equilibrium gaseous flows with shocks. Closure formulations based on both an interpolative approach as well as that based on a bi-Gaussian approximation for the distribution function are considered. Both closure strategies possess or mimic many of the desirable mathematical and computational features of closures following maximum-entropy principles on which they are based. However, in contrast to closures based directly on maximum-entropy concepts, the proposed interpolative and bi-Gaussian closures afford closed-form expressions for the closing moment fluxes and thereby avoid costly numerical solution procedures commonly associated with the latter. A Godunov-type finite-volume scheme with block-based anisotropic adaptive mesh refinement (AMR) is also described for the efficient solution of the resulting moment equations on multi-block body-fitted hexahedral mesh and the suitability and accuracy of the14-moment systems for describing non-equilibrium gaseous flows with shocks is demonstrated by considering several canonical flow problems, including planar shock structure.

Dynamic Models in Molecular Dynamics

Roman Gruzdev*, Arkadiy Soloviev**

*Southern Federal University, Rostov-on-Don, Russia, **Don State University, Rostov-on-Don, Russia

ABSTRACT

This work is devoted to the research of dynamic models of graphene based materials with molecular dynamics (MD) simulation. Our goal is to develop new methods for sample building and analysis and include those to the ACELAN-COMPOS software. Material of interest in current research – graphene – was chosen due to its unique physical properties. Main points of computer experiment are: to build molecular model of the sample; to investigate the model with LAMMPS software; to prove correctness of the results with ACELAN software. LAMMPS package was chosen as open-source up-to-date MD software with good computational potential and ACELAN with its ACELAN-COMPOS module is finite element analysis software developed at the Department of Mathematical Modeling of Southern Federal University. In MD simulation we apply specific loadings to the sample to perform amplitude-frequency analysis. After this step we perform the same analysis in ACELAN-COMPOS, thus we obtained 2 sets of frequencies. By applying statistical analysis we concluded that results are correct and in correspondence with other works.

Investigating the Effect of Local Vision-Guided Scleral Remodeling on the Development of the Eye

Rafael Grytz*, Mustapha El Hamdaoui**, Keyur Savla***

*University of Alabama at Birmingham, **University of Alabama at Birmingham, ***University of Alabama at Birmingham

ABSTRACT

It is thought that the retina can detect defocus and alter scleral remodeling to match the eye's size to its optics during development, producing eyes with good focus (emmetropia). Extensive evidence from animal studies shows that this emmetropization mechanism can adapt the eye's size to an experimentally altered focal plane using a powered lens. Clinical trials have attempted to use this mechanism for myopia control by prescribing lenses that are less powerful than needed to correct for the existing myopia. A myopic eye is too long for its own optics. Instead of slowing the myopia, the undercorrection of children's vision accelerated myopia progression. We propose that species-specific differences in the peripheral defocus underlie this species-dependent response. We have further developed our multi-scale model of the tree shrew eye [1] based on the assumptions that scleral growth is globally controlled by genetic factors while scleral remodeling is locally controlled by genetic factors and local refractive error. We estimated the focal surface from refractive and biometric measurements of three eyes. The peripheral defocus (35 degrees off-axis) showed a myopic shift of -4.13 (1.40D STDEV) compared to the central axis. Unlike tree shrews, humans often show a hyperopic shift in the periphery. We computed the local refractive error at the anterior surface of the sclera and transfered it to each scleral finite element using a mesh free approach. We simulated the emmetropization process from 24 to 180 days of visual experience (DVE). The simulation replicated the normal development of a tree shrew eye in good agreement with experiments. When the overall defocus was changed by using a negative powered lens, the eye adapted its size to precisely match the new focal surface. Inducing a hyperopic shift in the periphery by increasing the width of the focal surface by 50% at 24 DVE lead to -3.3D myopia at 180 DVE. Undercorrecting for the peripheral defocus-induced myopia by using a -2D lens (starting at 90DVE) increased the final myopia to -4.9D at 180DVE. Our results suggest that eyes with a myopic shift in the periphery (such as tree shrews) emmetropize well even if the overall defocus is altered. Eyes with a hyperopic peripheral shift (such as humans) tend to become myopic and undercorrection can lead to more myopia. This is the first model that provides a plausible explanation for this species-dependent response of the emmetropization process. [1] R Grytz, M El Hamdaoui. J Elast 2017;129:171-195.

Assessment of Wall Stresses and Internal Mechanical Heart Power in the Left Ventricle

Matthias Gsell*, Gernot Plank**

*Medical University of Graz, **Medical University of Graz

ABSTRACT

Introduction: Aortic valve disease (AVD) causes pressure and volume overload of the left ventricle (LV) which may trigger adverse remodeling and precipitate progression towards heart failure (HF). As myocardial energetics can be impaired during AVD, LV wall stresses and mechanical heart power provide a complementary view on LV performance which may aide in better assessing the state of disease. Objectives: Using a high resolution electro-mechanical (EM) in silico model of the LV as a reference, we evaluate clinically feasible Laplace-based methods for assessing LV wall stresses and mechanical heart power. Methods: We used N=4 in silico finite element (FE) EM models of LV and aorta of patients suffering from AVD. All models were personalized with clinical datasets under pre-treatment conditions. LV wall stresses and mechanical power were computed accurately from FE kinematic data and compared with clinically feasible estimation methods which were applied to the same FE model data. Results and Conclusion: Simulation results showed fundamental discrepancies between Laplace stress and internal mechanical power with the corresponding FE-based analogues, but Laplace-analysis provided sufficiently accurate estimates of mechanical peak power for clinical application. Further, external hydrodynamic power computed from synchronously recorded pressure-volume (PV) data in the LV cavity and internal mechanical power computed from LV deformation yielded essentially identical results since power expenditure during isovolumic phases was small. Thus both approaches either based on PV or Laplace analysis, are suitable for estimating peak mechanical power of the LV non-invasively, given that sufficiently accurate estimates of LV peak pressure are available.

Peridynamic Analysis of Impact Failure for Concrete Gravity Dam

Xin Gu*, Qing Zhang**, Erdogan Madenci***

*Hohai University; University of Arizona, **Hohai University, ***University of Arizona

ABSTRACT

Peridynamics (PD) is an alternative approach to the classical continuum mechanics. It is based on nonlocal interactions. The PD form of the equation of motion appears as an integral-differential equation instead of partial differential equations [1]. Especially the bond-based peridynamics (BB PD) has proven robust in analyzing crack growth and progressive failure of structures under extreme loads. However, the BB PD has the fixed Poisson's ratio restriction, which is fixed to 1/4 in three-dimensional problems and plane strain problems, and 1/3 in plane stress problems. The conjugate BB PD model introduced by Wang et al. [2] is one of extensions of the traditional BB PD to overcome this limitation. In the conjugate BB PD, the nonlocal interaction forces are not only related to normal stretch of bonds, but also related to rotation bond angles of a pair of conjugate bonds. In present study, we will further develop the conjugate BB PD model to analyze the projectile impact failure and penetration problems of concrete gravity dam. Description of damage and failure process of dams under projectile impact and blast-impact objectively is a significant but difficult issue [3]. A dam suffers from the effects of gravity and hydrostatic pressure when the reservoir is full. The process of a projectile impact on the dam at different positions will be simulated after static deformation analysis. The improved conjugate BB PD is found to be effective for simulating the projectile impact failure process of dams, which involves the crack nucleation, crack propagation, final fracture and local failure. Rate-dependent Fluid Behavior and Superficial Collagen as Protective Mechanisms of Kangaroo Shoulder Cartilage at High Strain-rates

Yuantong Gu*, Namal Thibbotuwawa**

*Queensland University of Technology, **The University of Adelaide

ABSTRACT

Aritcular cartilage exhibits complex mechanical behaviors such as strain-rate-dependency under external loading. It is believed that the interplay and interaction of cartilage constituents, i.e. proteoglycans, collagen and tissue fluid is the key reason for such complex behavior in cartilage tissues. In this study, we use the kangaroo as an animal model. Through integrating with experimental studies using kangaroo cartilage, a porohyperelastic numerical model with a strain rate-dependent permeability function is developed to understand the contribution of fluid on the strain-rate dependent indentation behavior. Comparison of the porohyperelastic models with constant, strain-dependent and strain-rate-dependent permeability models indicates a statistically significant contribution of rate-dependent fluid flow to the mechanical behavior, especially at high strain-rates. However magnitude of the contribution of the rate-dependent fluid behavior was small. Therefore it is hypothesized that superficial collagen of shoulder cartilage to have a higher contribution to its mechanical behavior. Mechanical properties extracted by calibrating a newly developed indentation equation on the experimental results of sequential enzymatic degraded proteoglycan and superficial collagen indicated that superficial collagen plays a more significant role than proteoglycans in facilitating the strain-rate-dependent behavior of shoulder cartilage. Contrary to the results in studies on knee cartilage, the superficial collagen is found to equally contribute to shoulder cartilage behaviour at all strain-rates, thus affirming its significance in the mechanical behavior of shoulder cartilage. Based on the results of the investigation, it has been concluded that, although fluid affects the tissue behavior at high strain-rates, mechanical indentation behavior is dominated by the contribution of the superficial collagen. However, stain limiting superficial layer in combination with rate-dependent fluid behavior can be attributed to protective mechanisms that reduces excessive deformation of the cartilage at large strain-rates.

Bio-inspired Scaffolds for Bone Grafting

Yucong Gu*, Arun Nair**

*University of Arkansas, **University of Arkansas

ABSTRACT

Ceramic implants are widely used in bone replacement and repairing the bone fracture. Every month, thousands of people need to undergo a surgical procedure called bone grafting to place an implant in their bones. It is a very complex surgical procedure, without a proper ceramic implant, it will pose significant health risks to the patient, or fail to heal properly. A good ceramic implant needs to have high porosity and large pore size to allow new bone cells to grow. However, a scaffold with higher porosity and larger pore size tends to reduce the mechanical strength. Thus, it is important to find a structural design, which allow the implant to have a high porosity and large pore size while retaining high strength. In this talk, computational models of bio-inspired scaffold are developed along with other common scaffolds and are subject to different loading conditions. The different geometries are tested under bending and compression loads to find the maximum stress and stress distribution. We predict the material properties based on density functional theory calculations, the effect of porosity in the material properties are modeled based on empirical relation by utilizing the density as the scaling factor. Our results show that the bio-inspired scaffold has relatively low stress levels when compared to other common scaffold structures. We also extend the study to test the bio-inspired scaffold with varying anionic and cationic substitutions occurring in the bone at the nanoscale. This study will provide an insight into a better scaffold design from bio-inspired structures and also the effect of substitutions on scaffolds.

On the Interplay Between Macroscopic Localization and Void Coalescence for Strain Rate Sensitive Materials

Vadillo Guadalupe*, Reboul Javier**, José Antonio Rodríguez-Martínez***, Shmuel Osovski****

*University Carlos III of Madrid, **University Carlos III of Madrid, ***University Carlos III of Madrid, ****Technion, Israel Institute of Technology

ABSTRACT

Significant progresses have been made in the last decades on the understanding and modeling of the micromechanics that govern the ductile fracture phenomena in porous metallic materials subjected to complex stress states. Two modes of plastic flow localization commonly occur in the failure of ductile materials. The first is the so-called “macroscopic localization” and occurs when the deformation becomes highly non-uniform and localizes into a thin band. The second one is the so-called “coalescence” and occurs when nearby microscopic voids interact and merge, leading to the formation of macroscopic cracks. The question addressed in the present work is whether macroscopic localization occurs prior or after the void coalescence. For that purpose, we have developed an original numerical methodology, based on 3D unitary-cell computations in ABAQUS/Standard, to simulate the evolution of a spherical void subjected to complex stress states: predefined Triaxiality and Lode parameters which remain fixed during loading. The key and original feature of our investigation, which is based on a previous work of Teko?lu et al., (2014), is to consider the strain rate dependence on the flow behavior of the material. We have identified that the viscosity of the material plays a crucial role on both localization modes. Nevertheless, irrespective of the material properties considered, our numerical results have shown that “macroscopic localization” occurs always earlier than “coalescence”. The implications and consequences of such behavior will be exposed and discussed.

A New Closed-form Method for the Inertia Force and Moment Calculation in Reciprocating Piston Engine Design

Nanxiang Guan*, Quanyong Xu**, Ming Zhou***, Zhifeng Xie****

*Tsinghua University, **Tsinghua University, ***Tsinghua University, ****Tsinghua University

ABSTRACT

The piston crank mechanism is an important component of the reciprocating piston engine, and it is an inherent vibration system. The calculation of the unbalance quantity is a critical procedure in the balancing mechanism design, which is adopted to balance the inertia loading. The traditional method usually used Taylor series expansion with crank-conrod ratio, then Fourier transform with the crank angle. The influence on the calculations resulting from the high order terms was generally ignored in Taylor expansion. However, the high order terms of Taylor expansion will also contribute to the low order terms in the Fourier series. This will induce poor precision in the inertia loading calculation, especially in the high crank-conrod ratio engine. This paper proposes a new closed-form method, which only adopts Fourier transformation. The coefficients of the Fourier transformation terms contain the contributions of all order terms of the crank-conrod ratio. Therefore, we name it as a closed-form method. Compared with the traditional method, the closed-form method could improve the numerical accuracy of the secondary reciprocating inertia force by 1.5% ~ 4%, when the crank-conrod ratio varies from 0.25 to 0.4. Using this new closed-form method to design a balancing mechanism, the primary and secondary reciprocating inertia forces can be completely balanced. For the engine, which the primary and secondary inertia forces are balanced, the ratio of the residual inertia force to the total force with the traditional method is 1.5%, while the ratio decreases to 0.5% with the closed-form method. The closed-form method is independent of the engine configurations?including centric engines and eccentric engine, single and multi-cylinder engines. This paper gives the applications in some cases as well.

Modeling of Ship-Wave Interaction Using Isogeometric Analysis Method

Pai-Chen Guan*, On Lei Annie Kwok**, Keng-Wei Chang***, Yang-Ling Lu****

*National Taiwan Ocean University, **National Taiwan University, ***National Taiwan Ocean University, ****National Taiwan Ocean University

ABSTRACT

The purpose of this study is to develop a numerical method that can solve the fluid-structure interaction (FSI) for near coastal ship behavior. The general structural response of ships is described by Mindlin plate theory and wave behavior is modeled by the shallow water equation. We propose the unified spatial discretization by using the Isogeometric analysis method (IGA) for both structure and fluid. The ship structure IGA method is the standard approach follows Galerkin weak form. And the IGA method for solving shallow water equation is using strong form collocation method with special discretization procedure. First, we place the collocation points at the maximum of each shape function on the parent domain to avoid the local rank deficiency. Then we introduce the non-conservative form of shallow water with flux splitting algorithm. A quasi-upwind scheme is developed to maintain the stability and regain the high order accuracy of NURBS shape functions. The proposed method is also proofed to have TVD characteristics by numerical experiment. The developed algorithm is applied to the standard sub-critical, hyper-critical flow for verification purposes. The IGA method shows robust behavior and high accuracy in those tests. Then, we test the numerical tank with ship structure floating and observe the ship motion and stress distribution.

Novel Fatigue S-N Models for Steel Reinforcing Bars with Pitting Corrosion

Xuefei Guan*, Jie Chen**, Jingjing He***

*Chinese Academy of Engineering Physics, **Beihang University, ***Beihang University

ABSTRACT

Abstract: Fatigue resistance of corroded steel reinforcing bars plays an important role in the safety of reinforced concrete bridges subjected to fatigue load and corrosive environment. This paper is concerned with modelling and estimating uncertainties in fatigue life of corroded steel reinforcing bars under constant amplitude loading. Novel S-N model formats incorporating the effect of corrosion degree ? (?-S-N models) are proposed based on linear elastic fracture mechanics. The proposed ?-S-N models consider the corrosion effect on fatigue life of steel reinforcing bar in a rational background of fatigue crack propagation. The performances of the proposed ?-S-N models are compared with the existing models in the literatures by Akaike Information Criterion (AIC), Bayesian Information Criterion (BIC), and Bayes factors. In addition, the applicability and selection of different models are discussed.

ABSTRACT

Numerical models can help to push forward the knowledge about complex dynamic physical systems. Turbidity currents are a kind of particle-laden flows that are a very complex natural phenomenon. Simply, they are turbulent driven flows generated between fluids with small density differences carrying particles. They also are one mechanism responsible for the deposition of sediments on the seabed. A detailed understanding of this phenomenon may offer new insight to help geologists to understand reservoir formation, a strategic knowledge in oil exploration. We present a finite element residual-based variational multiscale formulation applied to the numerical simulation of particle-laden flows in a Eulerian-Eulerian framework. Thus, the mathematical model results from the incompressible Navier-Stokes equation combined with an advection-diffusion transport equation. When sediment concentrations are high enough, empirical rheological relations close the model, describing how sediment concentrations influence the mixture viscosity. The central issue addressed here is to investigate, by computational simulations, the effects on the flow dynamics of one representative empirical rheological model. Two numerical setups, inspired by complex laboratory tests, are used for the analysis. The first is a tank with a lock-exchange configuration and the second employs a channel with a sustained current. Our findings suggest how turbulent structures and sediment deposition are affected by this empirical rheological law.

Adaptive Algorithm with Different Error Representations in Goal-Oriented Error Estimation

Diane Guignard*, Serge Prudhomme**, Vincent Darrigrand***, David Pardo****, Kenan Kergrene*****

*Texas A&M; University, **Ecole Polytechnique de Montréal, ***Basque Center for Applied Mathematics, ****Basque Center for Applied Mathematics, *****Ecole Polytechnique de Montréal

ABSTRACT

Goal-oriented error estimation is used when we are interested in a specific quantity of interest (QoI), say a linear functional of the solution of some partial differential equation, the so-called primal problem. Introducing its adjoint problem, with the QoI as right-hand side, the error in the QoI can be represented through the error of both the primal and the adjoint solutions. In practice, since these errors are unknown, a computable a posteriori goal-oriented error estimate can be obtained using for instance the solutions on a finer mesh. To be useful for adaptive strategies, the error estimate needs to be broken into local contributions and this decomposition is not unique. Even though the various error representations yield the same result globally, i.e. when summing all the local contributions, the local error indicators vary from one representation to another. Therefore, adaptive algorithms will perform differently depending upon the selected representation. The goal of this presentation is first to introduce different local error indicators for an abstract problem and then to compare their performance, when used in adaptive mesh refinement, through several numerical examples.

Stochastic Modeling and Sampling of Anisotropic Stored Energy Functions on Complex Geometries

Johann Guilleminot*, Brian Staber**

*Duke University, **Universite Paris-Est

ABSTRACT

This talk is concerned with the construction and efficient sampling of stochastic models for spatially dependent anisotropic stored energy functions. An information-theoretic formulation is first proposed to account for theoretical constraints related, for instance, to the mathematical analysis of the nonlinear stochastic boundary value problem. A sampling algorithm is subsequently constructed and relies on solving a set of stochastic partial differential equations. These equations depend explicitly on key geometrical features inherited from the manifolds defining the boundaries of the domain. Various applications on vascular tissues are finally presented to assess the relevance of the stochastic computational framework.

Micromechanical Analysis of Damage Events in Long Fibre Reinforced Composites (LFRCs) Using the Phase Field Approach of Fracture

Teresa Guillén*, Marco Paggi**, José Antonio Reinoso***

*PhD student, **full professor, ***associate professor

ABSTRACT

The design of composite structures in different engineering sectors requires the understanding of the different failure mechanisms that usually take plane in long fibre reinforced composites (LFRCs). Specifically, inter-fibre (matrix) failure is one of the principal failure mechanisms of such materials at the micromechanical level. The initiation of this physical phenomenon is generally located at the fiber-matrix interface and subsequently migrates into the matrix region. The coalescence of these fracture events is responsible for macroscopic failure, which generally provokes the reduction of the stiffness properties at the structural level. In this contribution, we investigate the onset and propagation of fibre-matrix decohesion and subsequent migration into the matrix by means of the novel numerical framework combining the Phase Field approach of fracture, for the bulk failure, and the Cohesive Zone model, for the fibre-matrix interface failure, as proposed in [1]. One of the central aspects of the current methodology regards its easy integration into any FE code suing a fully-implicit solution scheme. The obtained numerical predictions prove the robustness and versatility of the proposed numerical method, which allows the accurate prediction of fracture events from different signature in heterogeneous media to be performed. These results show an excellent accuracy with respect to experimental observations. Finally, these current simulations can be seen as a point of departure to construct a multiscale numerical framework within the context of the phase field approach of fracture for fibrous heterogeneous materials. Non-intrusive Implicit/implicit Coupling & ABAQUS Co-simulation

Stéphane Guinard*, Omar Bettinotti**, Robin Bouclier***, Jean-Charles Passieux****

*Airbus SAS, **Dassault Systèmes SIMULIA, ***Institut de Mathématiques de Toulouse, Université de Toulouse, ****Institut Clément Ader, Université de Toulouse

ABSTRACT

Non-Intrusive Coupling Techniques (NICT) open the field to a variety of new analysis capabilities (non-intrusive domain decomposition [1], 2D-1D/3D coupling [2], determinist/stochastic analysis). In particular, NICT may meet the challenges of industrial multi-scale analysis of large aero-structures: it allows investigating local structural non-linearities, while avoiding any human intervention on existing global models. This is a significant step beyond when compared to existing numerical technologies, which may already afford the coupling of different structural models (sub-modeling), but remain penalizing in terms of operability; or which are valid only within limited domains where local non-linearities do not affect the global behavior significantly. Significant industrialization efforts and dissemination towards AIRBUS stress analysis community will be reported here: implementation of NICT as a global to local, implicit to implicit coupling engine into ABAQUS was managed, relying on co-simulation and adapted meshing strategy. Specific needs of civil aircraft structural engineering have been addressed: global shell to local solid modeling, linear orthotropic elasticity at global scale to damage and failure of composite materials at local scale. Attention was paid to consider models actually representative of day-to-day stress analysis exercises, which involve geometrical complexity, large number of dofs, mixture of element types (shell, connectors & solid), assembly of parts through imposed kinematical constraints. Critical sources of local non-linearity have been considered in local models: contact, damage and failure of composites, captured through adapted solid meshes (discretization at meso-constituents scale, plies & interfaces) and relevant constitutive models. The advent of NICT capabilities into FEM industrial software lays the path to future evolution of industrial design & certification processes. State-of-the-art series of models, from global rough representations to local critical details, are usually processed through top-down analysis paths, with restrained capability of bottom-up updates: outcomes from detail simulations are not leveraged properly at global level. Both local and global models could now be processed jointly, bridging different levels of abstraction together, and enabling real-time forwards and backwards analysis. Such intended "multi-level structural analysis process" will be exemplified by re-exploring design & sizing exercises practiced on representative areo-structures. ABSTRACT

Fluid structure interactions with complex geometries are simulated using a finite element formulation coupled with several numerical techniques to ensure stability and accuracy. First, an edge based error estimator for anisotropic mesh adaptation is used to detect automatically all flow features and boundary layers. A Variational MultiScale stabilized finite element method is employed to solve the Navier-Stokes equations. Finally, an immersed volume method is proposed to deal with fluid-structure interactions. This paper is meant to show that the combination of anisotropic meshing with stabilized finite element methods provides an adequate framework for solving turbulent flows past immersed complex geometries at high Reynolds numbers. Several 3D challenging test cases and comparisons are proposed, such as flow past an airship, a drone and a flying car.

Near-Structure Air Blast Simulations Using Zapotec, A Coupling of CTH and Sierra/SM

Arne Gullerud*, Dave Hensinger**, Tim Shelton***, Edmundo Corona****

*Sandia National Laboratories, **Sandia National Laboratories, ***Sandia National Laboratories, ****Sandia National Laboratories

ABSTRACT

The ability to conduct simulations for air-blasts and their subsequent interaction with structures is vital in the study of a range of security and safety concerns. For significant stand-offs between the blast and the structure, a range of analytic/simplified simulation techniques can provide suitable results, e.g. conwep [1] for simple geometries. However, for blasts which originate close to the structure or with complex geometries, the interaction of the explosive products, air shock, structure geometry, and material failure necessitate the use of more complex computational frameworks. Zapotec [2], an Euler-Lagrange code which couples the hydrocode CTH with the structural transient-dynamics finite element code Sierra/SM, provides such a framework. This presentation includes a short overview of the Zapotec code methodology, and then compares Zapotec simulations to two simple test series which investigate structural response to explosive detonations with small standoffs where analytic/simplified simulation techniques can fail. The Zapotec simulations compare well to the experimental results in both cases, giving confidence in the use of Zapotec for near-structure air-blast scenarios. The presentation concludes with a demonstration simulation of explosive blast on a large-scale structure. Analytical Solution of Torsional Vibration of Uniform Circular Shaft with Multiple Concentrated Inertias

Jing Guo*

*Department of Engineering Mechanics, College of Aerospace Engineering and Civil Engineering, Harbin Engineering University

ABSTRACT

In the existing literature, many methods have been proposed to obtain the natural frequencies and modes of the vibration of uniform circular shaft with multiple concentrated elements. The torsional vibration problem was solved by using the Holzer method decades years ago.This problem was tackled by transfer matrix method and the finite element method after the rapid development of computer technology. The methods mentioned above are approximate solutions, their results are not accurate. Until 1975 (and 1979), Gorman (and Blevins) presented a new method to obtain the exact expressions of the natural frequencies and mode shapes of a uniform shaft carrying a single rotary inertia or torsional spring. In 1988, Rao gave the exact expressions for the torsional frequencies and mode shapes of the generally constrained shafts and piping with two disks. Ref. studied the torsional vibration problem of beam containing lumped elements under cantilever boundary conditions and fixed boundary conditions. As for the exact solutions of the torsional vibration of uniform shafts carrying multiple concentrated, the information concerned is rare. Only Chen presented an exact solution for free torsional vibration of a uniform circular shaft carrying multiple concentrated elements adopting the numerical assembly method, but it is still a approximate approach. In this paper, A new analytical method (AM) was used to perform the torsional vibration analysis of a uniform circular shaft carrying multiple concentrated elements (rotary inertias) with arbitrary magnitudes and locations. Three boundary conditions were studied: free–free, clamped–free and clamped–clamped. Several general rules were obtained, and the cause of the explanation was given. And it has been found that the agreement between the present results and the lumped mass method (LMM) results is good. Compared with existing method, the presented AM may be one of the simplest tools for studying the title problem.

Numerical Simulation Method Study for Inconel 718 Plate Penetration

Weiguo Guo*, Xueming Tan**, Longyang Chen***, Tuo Wang****, Yanping Li*****

*School of Aeronautics, Northwestern Polytechnical University, **School of Aeronautics, Northwestern Polytechnical University, ***School of Aeronautics, Northwestern Polytechnical University, ****School of Aeronautics, Northwestern Polytechnical University, *****School of Aeronautics, Northwestern Polytechnical University

ABSTRACT

Abstract: In modern aeroengine, the aviation regulatory agency require that all commercial turbine jet engine must include a strong blade containment system. This containment system usually consists of a thin metal casing designed to safely contain debris in the event of engine blade fragmentation. Inconel 718 nickel base superalloy is widely used in the manufacture of aeroengine casing. In the present study, to obtain real Johnson-Cook constitutive model and failure criteria parameters, a series of uniaxial compression and tensile tests of this material over a wide range of strain rate and temperature are carried out firstly. Then, with the help of Abaqus commercial software, the ball projectile and the Inconel 718 Plate are optimized for reasonable Hypermesh design, and then the parameters of Johnson-Cook constitutive model and failure criteria from experiments are employed to simulate different penetration conditions. To analyze and valuate the simulation accuracy and calculation methodology, a lot of the ballistic impact tests on Inconel718 target plates are also conducted. Moreover, the deformation and damage of the impact samples are Macro and micro analyzed by optical microscope and SEM. The numerical results of different simulation conditions (i.e. failure criteria, mesh qualities and boundary conditions) are compared with test results on ballistic impact. An ideal and higher precision results are obtained by elaborating adjustment for simulation process. Based on these results, it can conclude that, the combination of ductile fracture criterion and shear fracture criterion is better than the single Johnson-Cook failure criterion to obtain better simulation results; the fine mesh size (0.35mm) can better reflect the failure mode around the penetration hole than the coarse ones, and completely fixed boundary has a better performance than which partial fixed on predicting the overall deformation. Moving Morphable Component (MMC)-based Explicit Topology Optimization-some New Developments

Xu Guo*, Weisheng Zhang**

*Dalian University of Technology, **Dalian University of Technology

ABSTRACT

Moving Morphable Components (MMC) method, which does topology optimization in an explicit and geometrical way, is a new computational framework for structural topology optimization. Unlike traditional solution frameworks, where topology optimization is achieved by eliminating unnecessary materials from the design domain or evolving the structural boundaries, a set of morphable components are used as building blocks of topology optimization in the MMC framework and optimal structural topology is obtained by optimizing the shapes, lengths, thicknesses, orientations and layout (connectivity) of morphable structural components. The advantages of the method are that 1) it can integrate the size, shape, and topology optimization in CAD modeling systems seamlessly. 2) The method can combine both the advantages of explicit and implicit geometry descriptions for topology optimization. 3) It also has the great potential to reduce the computational burden associated with topology optimization. The proposed work introduces some new developments of the MMC-based method, including solving large-scale three-dimensional topology optimization problem efficiently, additive manufacturing oriented design (self-supporting structure design, minimum length scale control and graded lattice structure design), topology optimization with multiple materials, explicit control of structural complexity, kirigami pattern design of complex 3D structure and so on. Some representative examples are presented to illustrate the effectiveness of the proposed method.

Discrete Element Modeling of Flexible Fiber Flow and Heat Transfer in a Rotating Drum

Yu Guo*, Fan Yang**, Hanhui Jin***

*Department of Engineering Mechanics, Zhejiang University, Hangzhou, China, **Department of Engineering Mechanics, Zhejiang University, Hangzhou, China, ***Department of Engineering Mechanics, Zhejiang University, Hangzhou, China

ABSTRACT

Rotating drums have been frequently used to dry granular materials. The rotation of horizontally-arranged cylindrical drum about its major axis drives the materials inside it to flow and mix, facilitating the contacts and heat transfer between particles and drum wall surface. A flexible fiber model incorporated with heat transfer models has been developed for the studies of flow and heat transfer of flexible fibers in a rotating drum, which are much less understood than those of rigid spheres. In the simulations of rotating drum with flexible fibers, we look at contact number per fiber (coordination number), fiber movement trajectory, velocity distribution, temperature distribution, and heat transfer rate. The effects of some important fiber properties, such as fiber bending elastic modulus, fiber aspect ratio, fiber-fiber friction coefficient, and fiber-drum friction coefficient, on the fiber flow and heat transfer are explored. The knowledge obtained from the computational simulation studies is expected to guide the design and optimization of a rotating drum device for drying the flexible fibrous materials, such as textile and biomass materials.

Parameterized Grillage Model and Computational Method of Steel-concrete Composite Waffle Floor Systems Based on Numerical Simulation

Yu-Tao Guo*, Mu-Xuan Tao**, Xin Nie***, Jian-Sheng Fan****

*Key Lab. of Civil Engineering Safety and Durability of China Education Ministry, Dept. of Civil Engineering, Tsinghua University, Beijing, China 100084, **Associate Professor, Key Lab. of Civil Engineering Safety and Durability of China Education Ministry, Dept. of Civil Engineering, Tsinghua University, Beijing, China 100084, ***Key Laboratory of Civil Engineering Safety and Durability of China Education Ministry, Dept. of Civil Engineering, Tsinghua University, Beijing, China 100084, ****Beijing Engineering Research Center of Steel and Concrete Composite Structures, Dept. of Civil Engineering, Tsinghua University, Beijing, China 100084

ABSTRACT

A steel-concrete composite waffle floor system (SCCWFS) that consists of orthogonal steel beams and a flat RC slab has potential applications in long-span building floors because of its large loading capacity, low depth-to-span ratio, and excellent ductility, as demonstrated by a previous experimental program. According to the test results, the spatial composite effect between the orthogonal steel beams and concrete slab significantly influences the performance of the SCCWFS. However, the complexity of the spatial composite effect in the SCCWFS makes it much more difficult to determine the rigidity and the internal force distribution in a routine design practice than the one-way steel-concrete composite floor or the RC waffle slab. To address this problem, a parameterized grillage model is developed in which intrinsic factors are defined to describe the critical properties of the deformation pattern, the reaction force and moment distribution of the SCCWFS; relation factors are defined to relate these properties of the SCCWFS to that of its corresponding steel grillage. Based on the parameterized grillage model, parametric analyses are conducted using a beam-shell mixed finite-element (FE) model and the influence of various parameters on intrinsic and relation factors is investigated, in which the beam height, slab thickness, length-to-width ratio, and so on are shown to be of importance. Based on the batching modelling technique developed in this paper, the data of a total of 5190 numerical models associated with seven parameters covering almost all the practical cases are then obtained. A step-shaving method is then proposed to derive formulas, which is based on the method of analysis of regression and could act as a powerful tool to deal with models that are influenced by multiple variables and the analytical form could not be directly obtained. Based on the parameterized grillage model and the step-shaving method, computational formulas to predict the vertical displacements, reaction force and moment distribution of the SCCWFS are derived and verified. Finally, design procedures, recommendations and simplified forms of the formulas are proposed, in which the formulas are proved to have an error of approximately 10%.

ABSTRACT

ABSTRACT Following a series of recent innovations, isogeometric analysis for trimmed thin shell surfaces is currently developing into an accurate, efficient and mature design-through-analysis methodology. Based on a series of recent publications on the topic, we identify four key components for establishing a successful isogeometric methodology for trimmed shell analysis: (1) an efficient and accurate isogeometric shell technology, (2) methods to enforce boundary and coupling conditions at non-matching trimming curves, (3) quadrature methods for the integration of stiffness and residual forms in trimmed elements and along surface-to-surface intersection curves, (4) and the ability to query accurate geometric information related to trimmed surfaces and surface-to-surface intersection curves from CAD data structures. The first three components have profited from significant progress in both isogeometric and embedded domain finite element methods in recent years. The fourth component, the interaction of trimmed shell analysis with CAD data structures, is essential for demonstrating the competitiveness for complex real-world trimmed objects. This work contributes to this emerging technology with respect to the following aspects. On the analysis side, we present a robust variationally consistent Nitsche-type formulation for thin shells at large deformations that weakly enforces coupling constraints at trimming curves. On the geometry side, we present a set of algorithms that enable automatic interaction of trimmed shell analysis with CAD data structures based on the STEP exchange format. We integrate these methodologies in a comprehensive framework for isogeometric trimmed shell analysis. We demonstrate that our framework is able to seamlessly perform large-deformation stress analysis of an industry-scale 76-patch surface model of a Dodge RAM hood, while delivering comparable accuracy with respect to Simulia's commercial software package Abaqus. Simulation of Lipid Membrane Rupture via Cellular Automation

Abhay Gupta*, Irep Gozen**, Michael Taylor***

*Santa Clara University, Department of Mechanical Engineering, **University of Oslo, Centre for Molecular Medicine Norway, ***Santa Clara University, Department of Mechanical Engineering

ABSTRACT

Biological cell membranes consist of many organized phospholipid molecules. Rupture, i.e. the forceful opening of large area pores, in these membranes is a common form of cell damage, and irreversible rupture has been implicated in disease, e.g. muscular dystrophy. Understanding and perhaps controlling membrane pore formation would be promising not only in disease treatment and prevention, but also in applications such as gene therapy and drug delivery. Previously, only circular pores were known to form in biological membranes. However, recent experimental study of model bi-layer lipid membranes spreading on solid supports has led to the discovery of two new rupture modes: fractal and floral [1]. These modes share at least a qualitative similarity to the interaction of immiscible fluids in porous media (e.g., viscous fingering and invasion percolation). What is poorly understood are the reasons a membrane might prefer to form one type of fracture pattern rather than another. It is hypothesized that heterogeneous mechanical pinning (i.e., adhesion) between lipid bilayers governs this preference. Unfortunately, the very small fluid volume entrapped between the layers, as well as the difficulty in controlling the number of pinning sites, poses limits on the experimental investigation of rupturing. To investigate these different rupture morphologies, we developed a numerical model based on cellular automation (CA). A cellular automation consists of a grid of that are assigned a specific state (e.g., a 0 or 1). These states evolve through the application of a few very simple rules. Despite their simplicity, CA are able to capture a range of complex behavior, even emergent behavior, in the areas of growth, aggregation, segregation, and percolation [2]. While CA have been of particular interest to, for example, the geological science and spatial simulation communities, its application to lipid rupture mechanics is novel. Our new CA incorporates rules from both standard percolation models and particle-based fracture methods. We demonstrate the CA via simulations of circular, floral, and fractal morphologies and show how these can be obtained through simple alterations of pinning density and behavior. An Integrated Computational Modeling Approach to Predict Joint Properties Obtained in Solid-state Joining of Dissimilar Materials

Varun Gupta*, Erin Barker**, Kyoo Sil Choi***

*Pacific Northwest National Laboratory, **Pacific Northwest National Laboratory, ***Pacific Northwest National Laboratory

ABSTRACT

Multi-material assemblies hold the key to achieve light weighting, enhanced performance, and functionality in automobiles, aircraft, and other manufacturing applications. The desired product performance is achieved by collectively utilizing the favorable properties of different materials. Joining of such materials using conventional welding techniques, however, poses a significant challenge owing to the large differences in the physical properties of the constituent components. In dissimilar metallic systems such as Steel-Aluminum or Magnesium-Steel, the traditional fusion based welding processes can lead to undesirable large and continuous intermetallic phases, due to difference in melting points of the two metal alloys being welded. Solid-state joining techniques like friction stir welding and high velocity impact welding provide a viable approach to join such dissimilar materials. The process of determining optimal welding process parameters that lead to a robust solid-state joint using a purely experimental approach is time-consuming and expensive. Computational tools play a key role in developing a predictive understanding of the resultant joint properties. We present an integrated finite element method based computational approach with experimental support to quantitatively describe process-structure-property relationships for solid-state joints. Such a scientific framework can help accelerate the development and deployment of these solid-state joining techniques for manufacturing applications.

Probabilistic Assessment of Aircraft Structural Reliability: Major Challenges and Opportunities

Mark Gurvich*

*United Technologies Research Center

ABSTRACT

This work is aimed to review major challenges associated with probabilistic assessment of structural integrity specifically for aircraft applications and suggest most promising ways for their mitigation. The review and corresponding analysis are based on publically available sources and experience covering a broad range of aircraft and rotorcraft primary load-bearing structures in uncertain conditions. Challenges of both fundamental general solutions and practical engineering implementations are considered and prioritized. Also, challenges of different natures, such as computational (e.g., numerical efficiency), physical (e.g., methodologies to predict random damage), and practical (e.g., limited statistical information on input data) are discussed and listed. Among down-selected major challenges are issues associated with a) assessment of structural integrity with very low probabilities of failure; b) efficient modeling of random load, usage and environmental conditions; c) stochastic fatigue modeling of aircraft structures; d) impact/ballistic modeling of aircraft structures as random phenomena; e) multi-scale methods developed specifically for probabilistic assessment; f) integration of probabilistic modeling with statistical input characterization; g) simplified "engineering" methods of probabilistic analysis and assessment; and so on. For the down-selected challenges, potential solutions critically assessed for either direct implementation or additional enhancement or as an opportunity for future consideration. Finally, major observations and conclusions are summarized in form of practical recommendations.

Numerical Modelling, Simulation and Validation of Icing on a Wind Turbine Blade

Gustaf Gustafsson*, Simon Larsson**

*Luleå university of technology, **Luleå university of technology

ABSTRACT

Today there is a strong development of wind power in northern Sweden, where risk for icing conditions is present. Icing of the blades leads to changing load conditions, production loss and risk of overloading the machine components. When the ice loose from the blades, the ice throw can lead to both physical damage and personal injury. Uncertainties around these issues threaten the planned expansion in the northernmost regions. Prediction of loads and production losses are of great importance for the durability and economy of wind power plants [1]. A thrust worthy numerical model of ice loads on wind turbines will be a valuable tool for minimizing the costs due to damage and production losses caused by icing. This work presents a numerical model for simulating ice accretion on a wind turbine blade in lab-scale. It is a multi-physic model with interaction of three phases: the air, the water droplets and the wind turbine blade. The air flow is modelled with incompressible fluid dynamics (ICFD), the water droplets in the air is modelled with the discrete element method (DEM) and the wind turbine blade is modelled with the finite element method (FEM). A two way coupling is used for the interaction between the air and the water droplets and between the air and the wind turbine blade. A freezing condition controls the ice accretion when the water droplets hits the wing profile. The simulation is compared with a lab-scale experiment of ice accretion of a wind turbine profile in a wind tunnel found in literature [2]. The experiment is well documented with well defined parameters such as: temperature, wind velocity, water content in the air, size of the water droplets, wing profile and angle of attack. Two simulations were done for two different angles of attack and validated by comparing ice profiles on the blades numerically and experimentally for the two cases. Similar ice profiles were found numerically and experimentally. [1] IEA Wind Recommended Practice 13: Wind Energy in Cold Climates, 2012. [2] C. Reduced Models for Uncertainty Quantification in the Cardiovascular Network via Domain Decomposition

Sofia Guzzetti*, Luis A. Mansilla Alvarez**, Pablo J. Blanco***, Kevin T. Carlberg****, Alessandro Veneziani*****

*Emory University, **Laboratório Nacional de Computação Científica, ***Laboratório Nacional de Computação Científica, ****Sandia National Laboratories, *****Emory University

ABSTRACT

The parameters that characterize reduced 1D models of the cardiovascular system (CVS) feature variability both between patients and within a single individual, depending on physiological conditions. Characterizing this variability via uncertainty quantification (UQ) studies on the CVS entails two major challenges: (i) the computational resources required by full 3D models may not be easily accessible by users (e.g., hospitals) due to practical limitations, privacy concerns, or time constraints; (ii) Reduced 1D models may be inaccurate in capturing anomalies of the physiology in the presence of cardiovascular pathologies like stenoses or aneurysms. This introduces additional (epistemic) uncertainty that should also be characterized. The objectives of this study are (I) to design UQ solvers tailored to the CVS that promote parallelism and scalability, and (II) to enhance the accuracy of 1D reduced models without incurring computational cost. The Domain Decomposition Uncertainty Quantification (DDUQ) approach [1] performs UQ at the subsystem level, and propagates uncertainty information encoded as polynomial chaos coefficients via overlapping DD techniques, allowing for a reduction of the computational time. The local cross-sectional dynamics discarded by 1D models can be retrieved via educated reduced models such as the Transversally Enriched Pipe Element Method (TEPEM) [2], or HiMod methods [3]. The main stream dynamics and the transverse components are solved by the Finite Element Method (FEM) and by Spectral Methods, respectively, to guarantee high accuracy at low computational cost. Preliminary results show that (i) The computational cost of UQ in the CVS can be drastically reduced by promoting the independence of the subsystems and avoiding full-system simulations; (ii) The solver is scalable; (iii) Educated reduced models improve the accuracy of any 1D solver, at approximately the same computational cost. A Stabilized Cut Discontinuous Galerkin Framework (cutDG): I. Boundary Value and Interface Problems

Ceren Gürkan*, Andre Massing**

*MSc., **Dr.

ABSTRACT

ABSTRACT We develop both theoretically and implementationwise a novel cut Discontinuous Galerkin framework (cutDG) by combining stabilization techniques from the cut finite element method [1] with the interior penalty discontinuous Galerkin methods (DG) for elliptic [2] and hyperbolic problems [3]. The domain of interest is embedded into a background mesh and can cut through it in an arbitrary fashion. The discrete discontinuous Galerkin related bilinear forms are only integrated those parts of the mesh entities which are inside the physical domain of interest. In contrast to the classical cell-merging/agglomeration approach, we augment the discrete bilinear forms by properly designed stabilization to guarantee optimal convergence and condition number estimates independent of the particular cut situation. We show that the stabilization terms have to satisfy only a few abstract assumptions and we discuss possible realizations. The theoretical properties are illustrated by a number of numerical experiments including convergence and condition number tests for elliptic boundary and interface problems as well as pure advection-reaction problems. High Precision Imposition of Essential Boundary Conditions in Isogeometric Analysis by a Generalized NURBS Representation

Alireza H. Taheri*, Krishnan Suresh**

*University of Wisconsin, Madison, **University of Wisconsin, Madison

ABSTRACT

Due to the non-interpolatory behavior of spline basis functions, treatment of non-homogeneous essential boundary conditions in isogeometric analysis (IGA) is non-trivial. Several techniques including weak imposition via variational methods, or strong imposition via fitting algorithms have been proposed e.g. [1,2]. However, since splines are inherently poor in capturing rapidly varying functions, these methods result in significant error for non-smooth or discontinuous boundary conditions. In this paper, we propose a new method for the imposition of non-homogeneous essential boundary conditions in IGA by the introduction of an extension of NURBS representation. The proposed generalization is obtained by decoupling the weights associated with the control points, along both physical and parametric coordinates. This brings the possibility of treating the out-of-plane weights of boundary control points in the appropriate parametric direction as extra design variables to better approximate the boundary condition, while maintaining the underlying geometry and its parameterization intact. A global approximation technique is then introduced by setting up a nonlinear least square optimization problem whose design variables are the out-of-plane coordinates and weights of boundary control points. Subsequently, the optimization problem is solved by employing the Levenberg-Marquardt algorithm, and the obtained optimal results are imposed strongly on the problem. As the numerical results demonstrate, this procedure dramatically improves the accuracy of imposition of essential boundary conditions. In particular, unlike the existing NURBS-based methods, the proposed algorithm is able to capture sharp variations and discontinuities in the boundary conditions close to machine precision even with a coarse discretization, and without increasing the multiplicity of knots, thereby maintaining higher order continuity of the solution over the whole computational domain. Several numerical examples are presented to demonstrate substantial superiority of the suggested approach compared to existing methods. [1] Wang D, Xuan J. ABSTRACT

In many contact application involving high pressure like the case of integrated bearing track for aeronautical applications, surface hardening are necessary to ensure wear resistance. Chemical treatment such as nitriding and carburizing are often chosen and performed. The hardening depth can reach 700µm and need grinding, tribo-finishing or other manufacturing processes to give the engineering surface the good surface states in relation with the finale application. In this paper, a FEM simulation of a combined turning burnishing (CoTuB) process is proposed in order to explain how and why, when rough turning and ball burnishing processes proceed simultaneously they can lead to a very high hardening level and a hardening depth two or three times higher than those obtained after nitriding or carburizing. Three-dimensional simulations of the turning process by an improved thermo-mechanical moving loading, and simultaneously the burnishing simulation by a rigid ball, allowed having a great idea of the heating and cooling history of elementary volumes on the surface and beneath it, related to the several revolutions. These information combined with the mechanicals actions imposed by the ball, can explain how the strain hardening occurs in those special thermodynamics conditions. They can also explain the physical mechanisms that are activated and why the hardening depth is increased after each revolution depending on the temperature dependence of the material behavior, the recovering rate of the ball and the process parameters. Residual stress state can also be determined by the propose FEM multiphysics simulations. They allow understanding how from a revolution to another, tensile residual stress, very close to the extreme surface, induced by turning process became progressively compressive when the ball burnishing proceeds. The final simulated residual stress profiles beneath the surface are then compared to those obtained by experimentations. Results are very surprising and very interesting. Till now, induced phenomena are well known for turning process and ball burnishing process when they are used separately. Surface integrity of the engineering surface in terms of hardening level and depth, residual stress, and so on, is very improve when those two well-known processes act together and simultaneously. This combination has surely a great future for very high accurate surface engineering applications with an increased lifetime of security mechanical parts among others.

Data Pruning of Tomographic Data for the Calibration of Constitutive Models: Application to a Resin-bonded Sand

William HILTH*, David Ryckelynck**

*Mines ParisTech, **Mines ParisTech

ABSTRACT

With the development and the generalization of digital image correlation (DIC) and digital volume correlation (DVC) techniques, the volume of data acquired has drastically increased. This raises new challenges, such as data storage, data mining or the development of relevant experiments-simulations dialog methods such as model validation and model calibration. Data pruning of the experimental results is a relevant solution, focusing on meaningful data while saving time and storage. We developed an objective method to reduce drastically the amount of data thanks to model reduction techniques. From experimental snapshots, containing the values of a given field (displacement, strain...) in all the sample at all time steps, and image correlation error maps, we can extract reduced basis and coordinates of the full experiment. These basis are used to build an experimental Reduced Domain (RD) where the data is actually needed or relevant with a modified hyper-reduction method. This RD can be completed with a chosen Zone Of Interest (ZOI), enabling to decide to keep the data where it seems worthwhile. The RID can only be 10% or 25% of the complete sample. Then, in order to simplify data exploitation and storage, we can only focus on the RD and the projection of the reduced basis on this new geometry, reducing drastically the amount of data stored. Moreover, keeping only the pruned experimental data still enables model calibration. They can be directly imposed as Dirichlet boundary conditions, with the use of an hybrid FEM/hyper-reduction method. The hybrid method calculations are 10 to 70 times quicker than full field FEM calculations. The method is applied for a model validation and calibration of a polyurethane resin-bonded sand sample studied in in situ X-Ray CT. The experimental RD was determined thanks to computed displacement field and and its uncertainty. Two elastoplastic constitutive models of gradual complexity were assessed. The procedure showed that the simpler approach failed to model correctly the complex behavior of the bonded sand and motivated the development of more sophisticated constitutive equations. This new model was successfully validated and calibrated.

Numerical Simulation Study on Failure Mechanism of Octet Architected Nanolattices Subjected to Bending Load

WEI HUANG*, PING LIU**

*School of Aeronautics, Northwestern Polytechnical University, 127 Youyi West Road, Xi'an 710072, Shaanxi, P.R.China, **Institute of High Performance Computing, 1 Fusionopolis Way, #16-16 Connexis, Singapore 138632, Singapore

ABSTRACT

Abstract: With the development in high-precision lithography and thin film sputter deposition techniques, the fabrication of large-scale metamaterials has enabled to implement. Nanolattices are fabricated in creating lightweight, strong, and damage-tolerant structural metamaterials which are made up of microscale tubes with nanoscale thickness [1]. Existing studies have found that the failure behaviour of metallic glass can occur brittle-to-ductile transition by reducing the sample size to the nanoscale [2]. For nano-architected metallic glass, it can take advantage of both structural and material size effects. Hence, the bending stiffness and failure behaviour of the metallic glass nanolattices with octet unit cells were investigated by using numerical simulations for 3-point bending test in this work. The force-deflection response curves of the nanolattices with crisscrossed hollow tubes related to different cross-section shapes, different wall thicknesses and different tube aspect ratios are obtained, respectively. The simulation results reveal that the mechanical properties of the nano architected metamaterial could be controlled by the structural configuration as well as the wall thickness, cross-section shape and aspect ratio of hollow tubes. It is seen that the thickness and cross-section shape of hollow tube have strong influence on the flexural strength and failure modes of the nanolattices subjected to bending load. By changing the thickness and ellipticity of hollow tubes, it’s possible to control the failure behavior (buckling, material yield and fracture) of the nanolattices. When the tube thickness is thick or the cross-section shape is prone to a circle, the nanolattices tend to fail due to the material yield failure and fracture. When the tube thickness is thin or the cross-section shape is prone to a squashed ellipse, the buckling of hollow tubes is more likely to happen in the nanolattices before the plastic damage occurred. The mechanical response of the nanolattices exhibit significantly ductility by reducing the aspect ratio of hollow tubes. The conclusions from the numerical simulations could provide the guideline for the optimization design of the nanolattices. Reference [1] Meza LR, Das S, Greer JR. Numerical Simulation Study on the Influence of Welding Induce Residual Stress to the Fatigue Crack Propagation Behavior

WEI HUANG*, Yu-E MA**

*School of Aeronautics, Northwestern Polytechnical University, 127 Youyi West Road, Xi'an 710072, Shaanxi, P.R.China, **School of Aeronautics, Northwestern Polytechnical University, 127 Youyi West Road, Xi'an 710072, Shaanxi, P.R.China

ABSTRACT

Abstract: Welding is a fundamental process in manufacturing marine structures. Welding induced residual stress and deformation is, however, inevitable due to non-uniform distribution of temperature and plastic yielding during welding process. Fatigue has been always a highly challenging and complex engineering issue which is faced by the maritime and offshore industry worldwide. However, the reported 3-D fatigue crack propagation results in welded joint obtained from finite element technique are scarce. In this work, a procedure to numerical simulation for the propagation behaviour of fatigue cracks in a 3-dimensional welded structure subjected to welding induced residual stress and fatigue loads was developed. Firstly, sequentially 3-D coupled thermo-mechanical finite element analyses were performed for the simulation of welding process to predict the temperature and residual stress distribution field in a complex welded component by using double ellipsoidal heat source model and the element birth and death technique. And then, a numerical approach based on the cohesive elements, modified Paris-Erdogan law and nodal release method was proposed to simulate 3-D fatigue crack growth process, in which the stress intensity factor at crack tip was calculated with the consideration of plasticity induced crack closure and the cohesive element model is employed to the formation of new crack propagation surface. The effects of welding parameters (including welding velocity, heat input and welding sequence) to the residual stress distribution in a 3D welded joint were investigated and the influences of welding residual stress to fatigue crack propagation behaviour and life were analysed based on numerical simulation. The simulation results reveal that the residual stress induced by welding significantly affected the fatigue life of the welded joint. The residual stress has a degradation effect on the fatigue cracks which are located at the interface zone of weld material and base material. It is seen that the fatigue crack propagation life of the welded joint significantly decreases by around 50% for the same fatigue loading when the residual stress is taken into account. This work can help estimate the fatigue life and structural integrity of complex welded structures in the marine and offshore industry. Reference [1] Fricke W. A Conservative, Entropic Multispecies BGK Model

Jeff Haack*, Michael S. Murillo**, Cory Hauck***

*Los Alamos National Laboratory, **Michigan State University, ***Oak Ridge National Laboratory

ABSTRACT

In this talk we present a conservative multispecies BGK model that follows the spirit of the original, single species BGK model by making the specific choice to conserve species masses, total momentum, and total kinetic energy and to satisfy Boltzmann's H-Theorem. We apply this model to the case of mixtures in dense plasmas where one of the species is electrons, which requires a quantum treatment of the collision model to take degeneracy effects into account. We also develop a complete hydrodynamic closure for the ionic case via the Chapman-Enskog expansion, including a general procedure to generate symmetric diffusion coefficients based on this model. We numerically investigate velocity and temperature relaxation in dense plasmas and compare the model with previous multispecies BGK models, and discuss the trade-offs that are made in defining and using them.

*Notre Dame University - Louaize, **Lebanese International University, ***ICAM Lille, ****University of Angers, *****IMT Lille Douai

ABSTRACT

Vortex generators are widely used for heat and mass transfer enhancement in multifunctional heat exchangers/reactors. Most of the studies focus on rigid vortex generators which generate a complex flow structure consisting mainly of streamwise vortices and hairpin like structures. It was shown that theses vortices enhance the mixing process between the different flow regions as well as the heat transfer. In this paper, numerical simulations are used to study laminar flow in a circular pipe fitted with several arrays of flexible vortex generators. Five arrays of four equally spaced trapezoidal vortex generators are inserted in a circular pipe and inclined in a reversed position opposite to the flow direction with a certain angle of attack. A periodic rotation of 45 degrees is applied to the tabs arrays. The vortex generators are flexible and can deform due to the periodic fluid forces applied on the surfaces of vortex generators. The tabs oscillate without the addition of any external source of energy except that of the flow itself. The flow structures are analyzed using the proper orthogonal decomposition (POD) technique and the effect of tabs oscillation on vortices creation, suppression and dislocation is analyzed in details. Heat transfer is also analyzed and quantified by taking into consideration the additional pressure losses caused by the tabs oscillations. It is shown that the Nusselt number was increased by about 118% in the flexible vortex generators case relative to the rigid tabs case.

Parallel–Adaptive Implementation of Asynchronous Spacetime Discontinuous Galerkin Methods

Robert Haber*, Amit Madhukar**, Volodymyr Kindratenko***, Reza Abedi****

ABSTRACT

We present a new parallel-adaptive implementation for asynchronous spacetime discontinuous Galerkin method for hyperbolic problems; see for example [1]. In order to circumvent synchronous bottlenecks that might prevent efficient use of next-generation exascale platforms, we set aside established techniques and abstractions of parallel computation, such as the domain decomposition method (DDM) and the bulk synchronous parallel (synchronous time marching) model, and replace them with a scalable, barrier-free asynchronous solution scheme and localized fine-grain spacetime adaptive meshing. We use the Tent Pitcher algorithm [2] to generate fully unstructured spacetime meshes that satisfy a causality constraint to enable locally implicit aSDG solutions. These involve local Galerkin projections on a sequence of spacetime patches (small clusters of spacetime finite elements) that inherit the stability of implicit solvers while the overall solution exhibits the linear computational complexity reminiscent of explicit methods. The duration of each patch is determined independently and is not restricted by the order of the local basis. The processes of constructing and solving patches are interleaved and naturally share the same granularity. Locality and shared granularity render most of the algorithm embarrassingly parallel. Advancing a conforming space-like front mesh through the spacetime analysis domain is central to the Tent Pitcher algorithm. We maintain the front mesh as a global data structure to avoid DDM load balancing, a major synchronous bottleneck. Aside from querying and updating the front mesh, the algorithm is embarrassingly parallel. Adaptive meshing is implemented via modifications of the front mesh that govern refinement and coarsening of spacetime patches. However, because we must maintain the conforming property of the front mesh, these adaptive modifications are not naturally local. We present a Lazy Refinement method, first proposed but not implemented in [2], that localizes adaptive updates to the front mesh. Thus, adaptive front modifications, spacetime patch generation, and patch solutions share a common granularity and are embarrassingly parallel. We describe a software architecture that implements this scheme and present numerical results that demonstrate excellent scalability on a shared-memory host. Progress toward a distributed implementation and meshing in three spatial dimensions and time will also be discussed. References: [1] R. Abedi, B. Petracovici, and R. B. Finite Element Framework for Simulating Two and Three-dimensional Viscoplastic Collapses

Elie Hachem*, Luca Sardo**, Anselmo Pereira***, Rudy Valette****

*MINES ParisTech - CEMEF - CFL research group, **MINES ParisTech - CEMEF - CFL research group, ***MINES ParisTech - CEMEF - CFL research group, ****MINES ParisTech - CEMEF - CFL research group

ABSTRACT

We propose a stabilized finite element framework able to compute two and three-dimensional free surface flows of highly viscoplastic fluids. We chose to focus on two kinds of viscoplastic flow models: the Bingham model, corresponding to the most usual one, and the $\mu(I)$ model, that was introduced to predict dense granular rheology. Momentum and mass equations have been solved by using the Variational MultiScale method, coupled with a regularization technique and anisotropic mesh adaptation. A convective self-reinitialization Level-Set method has been used as a multiphase tool for describing the interface evolution. The obtained results on viscoplastic column collapses show good agreement with literature results in two-dimensional flows, and we provide new three-dimensional flows results.

High-Accuracy Phase-Specified Strain Measurement for Heterogeneous Matter in Digital Image Correlation Using Strain Gradient: Second-Order Displacement Gradient Application

Youssef A. F. Hafiz*, Adrian Lowe**, Zbigniew Stachurski***, Shankar Kalyanasundaram****

*Ph.D. candidate, Australian National University, **Senior Lecturer, Australian National University, ***Professor, Australian National University, ****Professor, Australian National University

ABSTRACT

To obtain high-accuracy phase-specified strain field in Digital Image Correlation (DIC), a novel technique was developed using strain gradient calculation and numerical phase separation. This technique is introduced and verified to fulfill the need of a higher accuracy strain fields in heterogeneous or discontinuous matter especially in micro-scale mechanics. In this paper, the second-order displacement gradient application is performed using Lu et. al. procedure [1] to present the peak accuracy of the technique and its application in heterogeneous matter. In addition, this exercise is performed to highlight the importance of second-order displacement gradient in heterogeneous applications. For verification purpose, the strain field resulted from second-order displacement gradient using strain gradient and phase separation technique was compared to its correspondences; first, first-order displacement gradient; second, first and second-order before applying the technique; third, strain field resulted from Finite Element Analysis (FEA) and its images were used as input for all DIC results as a bench mark for the comparison. The resulted strain from the second-order displacement gradient after applying the technique showed closer values to the FEA compared to first-order. Highlights about the differences in heterogeneous application are presented and discussed. In addition, the resulted strain from first-order displacement gradient after applying the technique showed closer results to the FEA than second-order displacement gradient before applying the technique. This shows the effect of applying the strain gradient and phase separation technique on the resulted strain field in heterogeneous matter. This will allow micro-mechanics researchers to study a full Representative Volume Element using DIC in a high accuracy to verify their models. In addition, this is the only technique, according to the author’s knowledge, that results a full strain field including high-accuracy strain values at interfaces using DIC. Therefore, the interface mechanics researchers will be able to verify their models using DIC as well. [1] H. Lu; P.D. ABSTRACT

The floating/fixed ocean structures such as wind power plants and other structures on offshore have to be taken account of safety in rough sea and tsunami. It is necessary to predict behaviors for both structures and fluid. The structures in the ocean are subjected to forces from the fluid. Particle methods of fluid dynamics have advantages for safe analyses to defend from natural disasters which are tsunami etc. than other numerical methods. The smoothed particle hydrodynamics (SPH) method [1] which is one of the particle methods is applied to some problems of fluid dynamics and solid mechanics. The SPH methods are mainly utilized to a number of problems for the fluid dynamics. If the structures in the ocean will be subjected to the large deformation from the waves, the stress may exceed the yield stress in the structures. The elastic-plastic effects have to be taken into account for the behavior of the structures. In the present study, the behavior of the floating or fixed structures in the ocean are calculated by using the SPH method and the computational elastic-plastic calculation for structural analysis which is appropriate to the SPH method are presented. Surface-only Physics-based Animation of Fluids and Fractures

David Hahn*, Fang Da**, Christopher Batty***, Chris Wojtan****, Eitan Grinspun*****

*ETH Zürich, **Columbia University, NY, ***Waterloo University, ON, ****IST Austria, *****Columbia University, NY

ABSTRACT

In this talk we present two recent applications of boundary element methods in computer graphics, in particular in the area of physics-based animation. Surface-only simulation techniques can achieve high efficiency and favorable scaling with increasing resolution by eschewing volumetric discretization and performing computations solely on the surface of the physical domain. At present however, three-dimensional liquid phenomena are simulated with volumetric solvers largely due to numerical challenges introduced by the nonlinearity of the governing fluid equations and the high density ratio between liquid and air. In the first part of this talk, we present a surface-only technique for simulating incompressible, uniform-density liquids in three dimensions. The liquid surface is captured by a triangle mesh on which a Lagrangian velocity field is stored. Because advection of the velocity field may violate the incompressibility condition, we describe an orthogonal projection technique to remove the divergence, while requiring the evaluation of only two boundary integrals. The forces of surface tension, gravity, and solid contact are all treated by a boundary element solver, allowing us to perform detailed simulations of a wide range of liquid phenomena, including waterbells, droplet and jet collisions, fluid chains, and crown splashes. In the second part of this talk, we present a boundary element based method for fast simulation of brittle fracture. By introducing simplifying assumptions that allow us to quickly estimate stress intensities and opening displacements during crack propagation, we build a fracture algorithm where the cost of each time step scales linearly with the length of the crack-front. The transition from a full boundary element method to our faster variant is possible at the beginning of any time step. This allows us to build a hybrid method, which uses the expensive but more accurate BEM while the number of degrees of freedom is low, and uses the fast method once that number exceeds a given threshold as the crack geometry becomes more complicated. We show that our method produces physically reasonable results in standard test cases and is capable of dealing with complex scenes faster than previous finite- or boundary-element approaches. We believe that both of our contributions advance the applicability of boundary element based techniques to physics-based animation and visual effects productions.

Industrial Methods for G-equation Combustion Model on a 3D Polyhedron Mesh

Jooyoung Hahn*, Karol Mikula**, Peter Frolkovi?***, Branislav Basara****

*Advanced Simulation Technologies, AVL LIST GmbH, Austria, **Slovak University of Technology, Slovakia, ***Slovak University of Technology, Slovakia, ****Advanced Simulation Technologies, AVL LIST GmbH, Austria

ABSTRACT

In this presentation, we propose industrially optimized numerical schemes to solve the G-equation model in premixed turbulent combustion on a 3D polyhedron mesh. The governing equations are described by the Favre mean (G-equation) and the fluctuation (G-variance equation) of flame represented by a zero level set of continuous implicit function. The turbulent flame surface equations and the turbulent flame speed formulations make a closure of G equation and G-variance equation. The G-equation is a standard level set equation containing the advection, surface normal flow, and mean curvature terms. The proposed scheme has mainly three advantages. The first is that it numerically shows higher order of convergence on very limited unknown variables in 3D polyhedron mesh. The second is that it can be easily applicable to the 1-ring face neighborhood structure for a parallel computation which is the simplest decomposed domain. The third is that a time step restriction caused by the CFL condition is practically reduced by the proposed semi-implicit scheme. The first and second advantages are also shown in a propagation in normal direction [1]. In case of the G-equation, an extension of algorithm in [1] is presented with the advection and mean curvature terms on a polyhedron mesh. The G-variance equation does not allow turbulent diffusion normal to the mean flame front. From the conventional method in [2], an approximation of a tangential diffusion term is used. We compare the difference between the original tangential diffusion and the method in [2] mainly used in the combustion community. In premixed turbulent combustion engines, we would like to present a practical difference between a higher order method and a typical upwind method of solving the G-equation and G-variance equation. Standard numerical results of each velocity term in the G-equation are also illustrated. [1] J. Hahn, K. Mikula, P, Frolkovic, B. The Parametric HFGMC Micromechanics for Damage Analysis of Composite Materials and Structures

Rami Haj-Ali*, Jacob Aboudi**

*Tel-Aviv University, **Tel-Aviv University

ABSTRACT

A nonlinear formulation of the parametric high fidelity generalized method of cells (HFGMC) is offered for the micromechanical analysis 2D and 3D multiphase periodic composites (Haj-Ali and Aboudi, 2013) with evolving damage. The new analytical formulation and computational implementation of the parametric HFGMC is performed (Haj-Ali and Aboudi, 2016) with consideration for efficient nonlinear multi-scale computations. An average virtual work integral form is proposed for the HFGMC method which allows for the definition of a generalized internal resisting force vector along with its corresponding symmetric stiffness matrix. Unlike the nodal displacement-based finite element (FE), the HFGMC and its weak form are cast in terms of the work-conjugate average displacement and traction vectors, defined on the surfaces (faces) of the discretized volumes (subcels or elements). The HFGMC micromechanics is shown to be well suited for integrating the microplane theory for the fiber-matrix spatial and local nonlinaer and damage fields. Another implementation of the parametric HFGMC will be demonstrated for the multi-scale and damage analysis of laminated composite structures. To that end, a refined hexagonal-array repeating unit-cell (RUC) HFGMC micromodel for the unidirectional composite is used. Local fiber and matrix damage approaches are examined. The accuracy of the developed nonlinear multiscale approach is demonstrated by a comparison with experimental results available in the litreture of notched laminated composite structures

Structural Optimization of Efficient Thin Film Solar Cells Using Surrogate Models

Shima Hajimirza*

*Texas A&M; University

ABSTRACT

This work uses surrogate modeling for efficient optimization and design of nano-scale thin film solar cell structures with enhanced opto-electrical characteristics. Study of thin film structures that selectively respond to input irradiance requires solving complex electromagnetic and quantum level first principle simulations. These simulations are intense and time-consuming. Therefore design of efficient sub-wavelength thin film structures is a complex optimization of a function with extremely high computational cost. Surrogate modeling can be invoked to alleviate the computational burden of design by approximating the wavelength-dependent opto-electrical characteristics of nano-scale geometries using selected sampling data and learning. We demonstrate that this approach can be reliably used to design several thin film solar cells with enhanced conversion efficiency in times significantly shorter than conventional optimization techniques offer. We study multi-layer silicon-based solar cells as well as organic thin film cells infused with nano-particles. The studied structures all benefit from surface texturing which is a commonly used technique for increasing the optical depth of a semiconductor without increasing the physical depth, therefore increasing the overall photon absorption and carrier collection. The underlying mechanisms responsible for such modifications (e.g. surface plasmonic excitation) are complex and geometry dependent. We demonstrate that Artificial Neural Networks can be used to learn these mechanisms as a function of geometry and wavelength. The surrogate model can then be used reliably for consequent optimization and analysis.

Recent Efforts on Curved Element Mesh Adaptation

Morteza Hakimi Siboni*, Kazem Kamran**, Onkar Sahni***, Mark Shephard****

*Rensselaer Polytechnic Institute, **Rensselaer Polytechnic Institute, ***Rensselaer Polytechnic Institute, ****Rensselaer Polytechnic Institute

ABSTRACT

To maintain the rate of convergence of high-order methods in simulations over curved domains the mesh entities must be curved to the boundary with a sufficient order of geometric approximation. The application of high-order methods to problems with complex geometric domains requires the tool for the creation and adaptation of curved meshes. Building on previous efforts that focused on supporting quadratic curved element mesh adaptation [1], this presentation will overview efforts to extend those procedures to higher-order mesh geometry and improve curved anisotropic mesh adaptation. The most commonly used approach to create curved meshes is to employ the available straight-sided or linear mesh generation tools for the initial mesh and then apply operations to upgrade that mesh to the desired higher-order curved mesh. However, there are now mesh generation tools that generate at least quadratic curved meshes (e.g., [2]). A tool has been created that can accept a mesh with either straight-sided/linear or curved/quadratic elements and upgrade that mesh to a higher-order curved mesh. Note that the current procedure is limited to meshes for which curved boundaries are being approximated by triangular faces. In addition to curving mesh entities classified on the domain boundaries, this procedure includes identifying and fixing poorly shaped and invalid internal entities that are created as a result of curving the boundary entities. Poorly shaped or invalid entities are fixed by applying appropriate split, swap, collapse, and interior mesh entity curving operations. The same sets of operations are used in the mesh adaptation procedure that is driven by an anisotropic mesh metric field. Bezier mesh geometry is used internally in these procedures due to its ability to more effectively control the mesh geometry as well as to provide efficient algorithms and computation. These procedures are easily linked with high-order analysis codes, for example, ACE3P code that is used to model complex particle accelerator geometries and MFEM code that is used to simulate plasma heating in a tokamak device using complex antenna arrangements. On Asymptotic and Pre-asymptotic Convergence Rates of Higher Order FE Methods

Harri Hakula*, Ivo Babuska**

*Aalto University, **University of Texas at Austin

ABSTRACT

The pointwise convergence of the Legendre expansion is of interest both theoretically through the application of the p-version of FEM. The known results in 1D and higher dimensions are asymptotic in nature, that is, concerned with p approaching infinity. In many cases, however, it is meaningful to consider pre-asymptotic behaviour where a well-defined convergence rate exists but is different from the eventual asymptotic one. In particular this is relevant in the context of engineering applications where the polynomial orders can be far from the asymptotic range. Our work is based on Wahlbin [1] and Saff and Totik [2]. Adaptive hp-method solvers must be able to make local changes both in the mesh (h) and the local polynomial order (p). Sobolev regularity estimation [3] is often used in determination of the local p. Sobolev regularity estimation is based on certain asymptotics of the Legendre expansion and thus may lead to ambiguous results if the local polynomial order is in the pre-asymptotic range. We illustrate this using benchmark problems including engineering application, thin shells of revolution and show the ultimate validity of the theorems. Computing hp-FEM simulations at very high polynomial orders requires non-standard solver technology. Our solver, based on Mathematica, supports integration using long floating point formats and in the case of constant coefficient problems also exact integration. We rely on Mathematica's builtin solvers for linear algebra. In this talk we emphasize the need for further work both in theory and construction of modern solvers supporting very high polynomial orders if the applications so require. [1]Wahlbin, L.B. ABSTRACT

We previously reported that a low-protein or a low-amino acid diet caused animals to develop fatty liver containing a high level of triglycerides (TG), similar to the human nutritional disorder “kwashiorkor”. Only a dietary arginine or threonine deficiency was sufficient to induce hepatic TG accumulation. However, supplementation of a low-amino acid diet with arginine or threonine failed to reverse it. In addition, we could not find any correlation between serum amino acid concentrations and liver TG level in terms of a single amino acid. So we dealt with individual data sets of serum amino acid concentrations as multi-dimensional vector data to conduct a comprehensive in silico analysis using machine learning programs. As an input data, we took data from a total of 135 rats which were fed various diets supplemented with 20 kinds of single amino acids. We carried out the Self-Organizing Map (SOM) analysis using only serum amino acid concentrations as input data which did not include the data on liver TG. By this analysis, we obtained a square map on which rats with similar serum amino acid profiles were successfully put near each other. Surprisingly, even though the classification was made only based on the data on serum amino acid concentrations, liver TG level was also smoothly classified, suggesting that the liver TG level was correlated well with a serum amino acid profile. Next, we applied another machine learning algorithm, multi-layer perceptron (MLP). We took serum amino acid concentrations of each rat as input data, and liver TG as output data. For learning, we made several MLPs whose numbers of mid-layers were 3, 4 and 5. After learning was completed, the serum amino acid concentrations of “unlearned” rats were put into each algorithm to obtain their output liver TG values. Then the obtained liver TG values were compared with measured actual liver TG values, and differences and error rates were calculated. As a result, higher number of mid-layers exhibited a lower error rate and individual hepatic TG accumulation levels could be predicted using just a data set of serum amino acid concentrations with good accuracy. In silico analysis succeeded in predicting liver TG level from the serum amino acid profile. Based on these results, we conclude that serum amino acid profile, which is sensed by hepatocytes, defined the hepatic TG levels.

Quantification of Multiscale Second-order Flow Structures in the Wake of a Square Wall-mounted Cylinder under Two Inflow Scenarios

Charlotte Haley*, Mihai Anitescu**, Christopher Geoga***

*Argonne National Laboratory, **Argonne National Laboratory, ***Argonne National Laboratory

ABSTRACT

Widely used methods for quantification of flow structures in turbulence such as proper orthogonal decomposition or dynamic mode decomposition provide an incomplete description of fully spatiotemporal flow dynamics, since they ignore the coupling between spatial and temporal oscillatory modes. Additionally, it is difficult to verify and validate the result of a simulation or compare with another simulation by looking at the modes alone. We propose a fully spatiotemporal approach to the problem of identifying spatially varying modes of oscillation in fluid dynamics simulation output by means of multitaper frequency-wavenumber spectral analysis. Two-dimensional spectrum estimation allows one to extract velocities of traveling waves and phase angles of standing waves in a section of data composed of one spatial dimension and one time dimension. Additionally, these estimates are accompanied by confidence intervals which allow one to assign significance in the direct comparison of two simulations' output in wavenumber-frequency space. This analysis applied to data obtained from simulation of a square wall-mounted cylinder under laminar and turbulent inflow conditions reveals widely different flow characteristics. Laminar inflow case data has a strong traveling wave in wavenumber-frequency space while turbulent spectra show more diffuse behavior with power in frequency-wavenumber space concentrated along a line corresponding to a turbulent energy cascade with velocity 0.95 nondimensional units.

Influence of Microstructure and Surface Roughness on Fatigue Initiation in Extruded Aluminum

Håkan Hallberg*, Sigmund Kyrre Ås**, Bjørn Skallerud***

*Lund University, Sweden, **Norwegian University of Science and Technology, Norway, ***Norwegian University of Science and Technology, Norway

ABSTRACT

Comprehensive experimental data on the fatigue properties of extruded Al6082-T6 is used together with crystal plasticity simulations to investigate the microstructure and surface roughness influence on fatigue initiation. The surface roughness of the specimens used in the experiments was mapped with White Light Interferometry (WLI) and the location of the fatigue initiation sites was identified and characterized in each sample. With surface geometries based on the WLI scans, densely meshed non-linear FE models were used to identify the locations of the highest macroscopic stress concentrations. A somewhat surprising outcome of the experimental study is that the majority of fatigue failures were initiated at surface irregularities that did not correspond to the most significant macroscopic stress concentration. Since the depths of the surface irregularities are comparable to microstructure features - such as the grain size - the present study explores to what extent microstructure variations can be a cause for the observed material behavior. The numerical investigation is performed by using crystal plasticity simulations and simulation models which are based on the actual surface geometries and material microstructures encountered in the experiments. Grain structure and texture are taken into account and the simulations reveal that variations in the microstructure can indeed make initiation of fatigue more likely to occur near surface notches that have macroscopic stress concentrations lower than maximum. Different frequently employed fatigue initiation parameters (FIP) are investigated and it is shown that a FIP based on a modified Fatemi-Socie criterion adds valuable information on local slip activity. The predictions obtained by using this criterion are to some extent conflicting with the results based on other FIPs, for example based on accumulated plastic strain or stored energy. A key observation is that macroscopic stress concentrations alone are insufficient and crystal plasticity simulations provide a competent additional tool in analyzing fatigue initiation mechanisms in polycrystalline samples. Not only the magnitude of stress concentrations, but also the stress gradients near surface irregularities appear as important aspects to consider when analyzing fatigue initiation. In addition, highly misoriented grain interfaces, which constitute significant barriers to plastic slip, provide internal domains in the material where initiation of fatigue damage appears more likely to occur than at the stress concentrations that are due to the surface roughness. The present investigation clearly highlights the importance of considering the influence of microstructure heterogeneities on fatigue properties in polycrystals.

Numerical Implementation of Viscoelastic Constitutive Models with Phase Evolution

Craig Hamel*, Jerry Qi**

*Georgia Institute of Technology, **Georgia Institute of Technology

ABSTRACT

Polymeric materials exhibit the phenomenon that new structures (such as crosslinking, crystal formation, or reformation of chains, etc.) are formed in a stress-free state. This aspect of these materials adds great complexity when deformation and polymerization occur simultaneously which is the case in many active polymeric material systems. We refer to this notion as phase evolution and view this idea as a cornerstone for the formulation of accurate constitutive models that capture the behavior of soft active materials. Previous literature regarding the mechanics of materials exhibiting phase evolution has been limited to hyperelastic constitutive models and has not included dissipative effects. This work examines the implementation aspects of numerically integrating a large deformation material model which exhibits viscoelastic properties as well as phase evolution. Due to the ever-increasing demand of efficient simulation based design this has limited the application of certain materials with complex multi-physical behavior such as shape memory systems. An efficient method for implementing such models would further the presence of active materials within industry. The major challenge is efficiently accounting for individual phases possessing different reference configurations and being able to track this complex mechanical response when the material is subjected to large deformations. To account for this material behavior a continuum based approach will be used to formulate a general finite strain framework that captures the coupling of the viscoelastic response with phase evolution. A naïve implementation of such a model proves to be computationally cost prohibitive as the number of phases and viscous state variables increases. This necessitates the development of a viscoelastic effective phase model (VEPM) to account for the effect the combined deformation histories have on the mechanical response. The VEPM reduces the number of state variables to a constant number for an arbitrary number of phases allowing for an efficient implementation in commercial FEM software. Both the naïve and VEPM implementation of the model will be compared for simple mechanical boundary value problems to verify the accuracy as well as a rudimentary convergence and running time studies. Finally, exemplary 3D finite strain simulations will be presented and compared to experimental results to verify the method.

A hysteretic constitutive model for dry woven composite fabric under large strain.

Nahiene Hamila*, Yvan Denis**, Eduardo Guzman-Maldonado***, Fabrice Morestin****

*INSA Lyon, **INSA Lyon, ***IRT Jules Verne, ****INSA Lyon

ABSTRACT

Draping composite reinforcement on non-developable shapes necessarily leads to deformations in the plane generating large shears between warp and weft. Sliding between fibers and between yarns creates friction that dissipates energy. This paper presents a constitutive model describing the dissipative behavior of 2D composite textile reinforcements under large strain. The model is based on two innovative points. First, the additive decomposition of Green - Naghdi is considered, which leads to write the yield function and the plastic law in a conventional manner. This is very uncommon for anisotropic fields. Secondly, nested surfaces according with Mroz Theory define the strong non-linearity of the problem. The use of these two points allows to define a flexible dissipative model for numerical simulations. The dissipation process driven by fibres friction is exclusively associated with the in-plane shear deformation mode. As a result, the material parameters are calibrated using standard methods, like the Picture Frame.

Direct Numerical Simulation of Turbulence Eddy Shocklets: Dependence of Small-Scale Statistics and Numerical Stability on Forcing Functions and Physical Configuration

Peter Hamlington*, Colin Towery**, Alexei Poludnenko***

*University of Colorado Boulder, **University of Colorado Boulder, ***Texas A&M; University

ABSTRACT

Eddy shocklets arise in compressible turbulent flows where turbulent velocity fluctuations become locally supersonic and lead to the formation of small-scale, weak, and unconfined shock-like structures. In practice, eddy shocklets can be expected to occur in high-speed compressible flows, such as exist inside scramjet engines, and are strongly moderated by viscous diffusion. As a result, the thickness of these eddy shocklets is of the same order as the Kolmogorov microscale of the flow. This is in distinct contrast to strong, confined shockwaves generated by the mean flow configuration, whose thicknesses scale with the local molecular mean free path. Despite being very weak shockwaves that can notionally be resolved by standard direct numerical simulation techniques, eddy shocklets represent a distinct challenge to the numerical stability and accuracy of monotonic and non-oscillatory numerical methods, including mature and popular shock-capturing schemes such as the Godunov finite volume method of corner transport upwinding with piecewise-parabolic reconstruction (CTU-PPM). In this talk, we present findings from several sets of three-dimensional direct numerical simulations (3D DNS) conducted to evaluate the effects of various kinetic and thermal energy forcing techniques to sustain compressible homogenous turbulence in an adiabatic domain, as well as to determine the required spatial, temporal, and statistical resolution to study eddy shocklets using the CTU-PPM reacting flow code Athena-RFX. We find that different large-scale kinetic energy forcing schemes can result in substantially different Mach number scaling and small-scale statistics of dilatational fluctuations generally, and eddy shocklets in particular. In agreement with previous literature, we find that the use of negative thermal energy forcing, which ensures statistical stationarity in an adiabatic domain, also leads to significant quantitative differences in dilatational dynamics. Finally, we compare results from simulations with different physical configurations, including different caloric equations of state, bulk viscosities, and Prandtl numbers.

Multi-Level Spectral Deferred Correction Scheme for the Shallow-Water Equations on the Sphere

Francois Hamon*, Martin Schreiber**, Michael Minion***

*Lawrence Berkeley National Laboratory, **University of Exeter, ***Lawrence Berkeley National Laboratory

ABSTRACT

The numerical modeling of global atmospheric processes is a challenging scientific application and requires accurate time integration methods for the discretized governing partial differential equations. These complex processes operate on a wide range of time scales, and often have to be simulated over long periods of time – up to a hundred years for long-term paleoclimate studies –, which constitutes a challenge for the design of stable and efficient integration schemes. We propose an efficient and high-order accurate implicit-explicit numerical scheme combining Multi-Level Spectral Deferred Corrections (MLSDC) with a spatial discretization based on the Spherical Harmonics (SH) transform to solve the shallow-water equations on the sphere. In MLSDC, a sequence of low-order corrections is applied iteratively to a provisional solution to achieve high-order temporal accuracy. The corrections are performed on a hierarchy of coupled space-time levels to shift the computational work to the coarse levels and reduce the cost of the integration. Our MLSDC scheme fully takes advantage of the features of the SH transform in the construction of accurate transfer functions between space-time levels as well as in the design of efficient solvers for the implicit systems. Using numerical examples, we show that our implicit-explicit MLSDC numerical scheme is stable for large time steps, and achieves up to eighth-order temporal accuracy. We also compare its computational cost to that of existing single-level implicit-explicit time integration methods.

A Hybrid Local/Nonlocal Continuum Model for Wave Propagation in Linear Elastic Solid

Fei Han*, Gilles Lubineau**

*Dalian University of Technology, **King Abdullah University of Science and Technology

ABSTRACT

In this paper, we apply a hybrid local/nonlocal continuum model to study wave propagations in the linear elastic solid. Through this hybrid model, the peridynamic model, which is a nonlocal continuum model, is applied to the key domain of a structure, where damage and fracture exists to cause the wave dispersions. In the rest of the structure, the classical continuum model is used to describe wave propagations without dispersions. The wave speeds of plane waves for low- and high-frequency are derived in different domains described by the pure local, pure nonlocal and hybrid models, respectively. The wave dispersions are plotted through the analytical and numerical solutions. The discrete formulation of the hybrid equations of motion is also described. Two-dimensional numerical examples illustrate the validity and accuracy of the proposed model. It is shown that the hybrid local/nonlocal continuum model can be successfully applied to simulate wave propagations in the linear elastic solid with a crack.

Effect of Microstructural Resolution in Virtual Samples on Property Evaluation of Cement Paste Using Crack Phase Field Model

Tong-Seok Han*, Ji-Su Kim**

*Yonsei University, **Yonsei University

ABSTRACT

Virtual specimens with complex random microstructures can be obtained from micro-CT. Depending on the length characteristics of the microstructural features, the detailed description of the microstructural features in the generated virtual specimens are influenced by the resolution or voxel size of the samples. When the virtual samples are evaluated using virtual loading tools, the maximum number of voxels in the virtual samples should be within the limit of plausible computation effort. Due to this limitation and to guarantee the representative volume of the evaluated samples, the degree of detailed microstructural description can be affected. This, in turn, can also affect the evaluated properties. In this study, effect of void microstructure resolution of cement pastes on the characterization and property evaluation is investigated. The virtual samples are prepared from the synchrotron micro-CT images, and the same data set with different resolutions are characterized and evaluated using the crack phase field model [1]. Through the analysis, the effect of resolution change on the microstructural characteristics and material responses (stiffness and tensile strength) is evaluated, and the characterization and the properties are correlated. The issue of selecting modeling input parameters for the crack phase field model is addressed, and the selected parameters are applied to cementitious materials with additional distinct microstructural features, i.e., cement paste embedded with glass beads. The modeling parameter selection process for virtual specimens, where distinct void microstructural features with different scales are present, is discussed. [1] C. Miehe, L.-M. Schänzel, H. DNS of Particle-laden Turbulent Channel Flow in Transitional Regime

Masaki Hanabusa*, Takahiro Tsukahara**

*Tokyo University of Science, **Tokyo University of Science

ABSTRACT

It is known that intermittent localized turbulence in a channel flow sustains in the form of oblique bands, so-called turbulent stripe [1]. The stripe pattern forms obliquely against the mainstream with an interval much larger than the channel gap and sustains steadily. Studies of such large-scale intermittent structures are important for understanding the subcritical transition process, but the robustness of the structure in multiphase flows has not been investigated. Pan & Banerjee [2] showed that small particles suppress sweep motions and large particles enhance them in the particle-laden turbulent flow. In the former case, another study also reported a particle-induced drag reduction [3]. However, it is still unclear whether the turbulent stripe would be formed or not in flows with small particles. In this study, we investigate the subcritical transition process in particle-laden channel flows with focusing on the stripe formation. We performed direct numerical simulations of pressure-driven plane channel flows with point particles, in which particle-particle interactions were not considered. The volume fraction of particles we tested here was low sufficiently to neglect the interactions. The particle motion was described by the Basset-Boussinesq-Ossen equation. Force on particles was considered as drag force to calculate the particle-fluid interaction. We investigated the effect of particles on the turbulent stripe, varying the Stokes number at a fixed volume fraction. In the one-way coupling simulation, we found that particle distribution was rather homogeneous in the wall-parallel direction even with the turbulent stripe. On the other hand, heavier particles accumulate near the wall even without gravity. In the two-way coupling, the stripe appeared to be disturbed and broken temporarily for the heavier particles. This result might be caused by particles accumulating near the wall. In the full paper, we would discuss the influence of interaction force on the fine-scale eddies in the turbulent stripe. Microstructural Finite Element Modeling of Discontinuous Fiber Reinforced Composites

Imad Hanhan*, Ronald Agyei**, Michael D. Sangid***

*Purdue University, **Purdue University, ***Purdue University

ABSTRACT

Fiber reinforced polymer composites are light weight and high strength materials, making their development desirable especially for the aerospace industry. However, their implementation hinges on large scale testing programs, which require thousands of specimen level experimental tests to qualify their mechanical properties. Combined with the fact that composite materials still have many unknown behaviors and failure mechanisms, it can be very complicated to certify the use of a composite material and model its mechanical behavior. A common practice for composite modeling is to homogenize the material properties for macro-scale applications, and use their predicted elastic properties – coupled with an internal damage parameter – to represent the mechanical response of the material. For discontinuous fiber composites, homogenization becomes even more complicated, due to extreme spatial heterogeneity in the microstructure. This work aims to model the behavior, including the damage evolution, of discontinuous fiber reinforced composites at the microstructural level. While not homogenizing the material increases the computational cost, it allows for identifying and modeling the heterogeneous deformation mechanisms and helps build confidence in the model's predictions. Preliminary work in this study is to instantiate the exact geometry of the microstructure from X-ray computed tomography (XCT) reconstructions, as well as to conduct linear elastic models of the exact microstructure. The model's prediction of deformation is directly compared to companion results from in situ XCT studies. This work aims to accelerate the qualification of fiber reinforced composite materials by developing enhanced predictive capabilities of the strength and failure mechanisms at the microstructural level. Overall, the results expand the current understanding of composite mechanical performance, and provide a methodology for multi-scale composite material modeling.

Numerical Solution for Nonlinear Random Vibrations of Beams with Fractional Derivative Elements

Zhaopeng Hao*, zhongqiang zhang**

*Department of Mathematics, Worcester Polytechnic Institute, **Department of Mathematics, Worcester Polytechnic Institute

ABSTRACT

In this work, we will talk about the numerical solution for nonlinear beam model under uncertainty with nonlocal damping. Specifically, we consider a stochastic beam equation with additive space-time noise with a time-fractional derivative modelling a damping effect. However, solving such an equation numerically is usually prohibitively expensive, even in one dimension. The main challenges are high cost of Monte Carlo simulation for realizations in random space and a large amount of storage due to the nature of the fractional derivative. To alleviate the difficulties, we develop a fast deterministic solver for the nonlinear stochastic beam model with reasonable computational cost and low memory storage. More precisely, we adopt an implicit-explicit scheme in time so that the nonlinear term is treated explicitly. With the time discretization scheme, we use a Fourier spectral method in physcial space which leads to fully decoupled stochastic ODEs. Thus the resulting scheme can be embarrassingly parallelized. Moreover, we approximate the fractional derivative by a fast L1 scheme with a low storage. Numerical example will be given to show the efficiency and accuracy of the numerical solution.

Spectral Behavior of Nitsche's Method

Isaac Harari*, Uri Albocher**

*Tel Aviv University, **Tel Aviv University, Afeka College

ABSTRACT

Incompatible discretization methods provide added flexibility in computation by allowing meshes to be unaligned with geometric features and easily accommodating non-interpolatory approximations. Such formulations that are based on Nitsche's approach to enforce surface constraints weakly, which shares features with stabilized methods, combine conceptual simplicity and computational efficiency with robust performance. The basic workings of the method are well understood, in terms of a bound on the parameter. However, its spectral behavior has not been explored in depth. In addition to the physical eigenpairs which approximate the exact ones, as in the standard formulation, Nitsche's method gives rise to mesh-dependent eigenpairs associated with weak enforcement of boundary or interface constraints. The dependence of the eigenvalues on the Nitsche parameter is related to a boundary quotient of the eigenfunctions (reminiscent of the Rayleigh quotient). Numerical studies show that, for the most part, the constraint eigenvalues exhibit essentially linear growth with the parameter, whereas the physical eigenvalues are virtually constant, in line with the values of the corresponding boundary quotients. This behavior sheds light on the role of the stabilization parameter in attaining coercivity for the Nitsche method. Departures from this behavior occur in specific veering zones, in which the eigenpairs lack clear type. Eigenvalue veering does not impair the performance of the method. The spectrum of a reduced system obtained by algebraic elimination contains only physical eigenpairs, and is free of veering. The favorable features of the reduced system warrant its use in the solution of boundary-value problems. To date, incompatible discretizations are rarely used for eigenvalue problems in engineering applications, possibly due to the potential presence of mesh-dependent constraint eigenpairs. Removing the added degrees of freedom on the boundaries addressed by the Nitsche approach by Irons-Guyan reduction is a relatively inexpensive procedure that preserves the essential structure of the underlying formulation, and yields a system that contains only physical eigenpairs. As such, the spectrum is virtually insensitive to stabilization beyond the threshold required for coercivity, preserving the conditioning of the standard formulation. Being free of the constraint eigenpairs, the Irons-Guyan reduced Nitsche formulation of the eigenvalue problem may be solved by any conventional eigenvalue solver. This procedure facilitates the use of Nitsche's method for formulating eigenvalue problems, and justifies its use in explicit dynamics.

Shear Transformation Zone Dynamics Simulations of Nanomechanical Experiments

Thomas Hardin*, Christopher Schuh**

*MIT, **MIT

ABSTRACT

Shear Transformation Zone Dynamics (STZD) simulations treat plastic deformation of metallic glass as a series of thermally activated, localized, discrete shear events. In STZD, shear events interact and their effects propagate on a continuum level, often modeled by the Finite Element Method. The shear events are controlled using Transition State Theory and the kinetic Monte Carlo method, enabling STZD simulations to cover experimentally relevant time scales. However, past STZD simulations have modeled samples of only a few tens of nanometers in any dimension, precluding side-by-side comparison with actual nanomechanical experiments. This talk presents STZD simulations on experimentally relevant length and time scales, and discusses the methods used to achieve such large sample sizes. Also, the role of free volume as a simulation state variable is discussed, with particular focus on tension-compression asymmetry. Finally, the challenges and opportunities in pairing STZD simulations side-by-side with experiments are discussed.

Multiresolution Adaptive Wavelet Solver for Nonlinear Partial Differential Equations with Error Control

Cale Harnish*, Karel Matouš**, Daniel Livescu***

*University of Notre Dame, **University of Notre Dame, ***Los Alamos National Laboratory

ABSTRACT

Simulations of practical engineering applications must solve coupled systems of nonlinear partial differential equations (PDEs), with features evolving on a wide range of spatial and temporal scales. This multiscale and multiphysics nature is a challenge for classical computational methods and may impose prohibitive computational requirements. To overcome these challenges, we have developed a novel multiresolution wavelet based algorithm to solve PDEs with significant data compression and explicit error control. Our proposed numerical method exploits the features of the biorthogonal interpolating wavelet family of basis functions, and second generation wavelets, to solve initial-boundary value problems on finite domains. We maximize the traditional data compression ability of wavelets by creating a unique multiresolution representation for each field, and using the minimum number of collocation points to define the coarsest resolution. Moreover, we compute spatial derivatives by operating directly on the wavelet bases. We provide a priori error estimates for the wavelet representation of fields, their derivatives, and the aliasing errors associated with the nonlinear terms in a PDE. Then, our estimates are used to construct a sparse multiresolution spatial discretization that guarantees the prescribed accuracy for each unknown. Our algorithm includes a predictor-corrector procedure within the time advancement loop to dynamically adapt the computational grid and maintain the prescribed accuracy of the solution of the PDE as it evolves. Furthermore, we present a simplified index notation for the wavelet operations to facilitate their matrix-free computational implementation. Our highly adaptive algorithm has been verified on a variety of nonlinear problems including Burgers' equation and the Navier-Stokes equations. Convergence to the analytical solutions is achieved at a rate which is in agreement with a priori estimates. Our algorithm provides accurate solutions to coupled systems of nonlinear PDEs with explicit error control, significant data compression, and fine scale features are well resolved with no spurious numerical oscillations.

Compressible Flow and Conjugate Heat Transfer Using Blended RBF Interpolation

Michael Harris*, Alain Kassab**, Eduardo Divo***

*University of Central Florida, Mechanical and Aerospace Engineering Dept., Orlando, FL USA, **University of Central Florida, Mechanical and Aerospace Engineering Dept., Orlando, FL USA, ***Embry-Riddle Aeronautical University, Department of Mechanical Engineering, Daytona Beach, FL USA

ABSTRACT

A meshless blended radial basis function (RBF) methodology is developed to solve conjugate heat transfer problems with convection to viscous compressible flow coupled with conducting solids. The radial basis function interpolation uses Hardy Multiquadrics which depends on a shape parameter and the shape parameter is typically chosen to be a large value rendering the RBF flat. The approach of choosing a large shape parameter tends to interpolate smooth data very well providing spectral accuracy in cases, although this approach tends to fail for steep gradients requiring the shape parameter to be lowered to capture the shock and prevent oscillations. The blended radial basis function method uses low shape parameter interpolation when shocks or steep gradients are detected and then switches to high value shape parameter RBF interpolation where the data is smooth. The blended RBF approach has proven to show stability and accuracy in many test cases. Numerical examples are presented to validate the approach of solving viscous compressible flow with conjugate heat transfer using the blended RBF methodology.

The Influence of Sacrificial Bonds on the Mechanical Properties of Soft Tissue

Markus Hartmann*, Huzaifa Shabbir**

*Computational Physics Group, Faculty of Physics, University of Vienna, Austria, **Computational Physics Group, Faculty of Physics, University of Vienna, Austria

ABSTRACT

Biological materials, like bone, wood, silk or the mussel byssus, often tailor their mechanical properties using reversible cross-links. These cross-links are weaker than the covalent backbone of the structures and, thus, normally fail before the backbone ruptures when the structure is loaded. This rupture of cross-links may expose some – previously shielded – part of the molecule to loading. This interplay of cross-link rupture and revealing of hidden length provides a very efficient energy dissipation mechanism leading to an elevated toughness of the structure. Because the cross-links “sacrifice“ themselves for the overall mechanical performance of the structure, they are also called “sacrificial bonds”. The reversibility of bonds means that sacrificial bonds may reform after the load is released. This mechanism ensures that the system recovers its original mechanical properties with time, providing some self-healing capabilities. In my talk I will present a computational model to study the influence of sacrificial bonds on the mechanical behavior of fibrous systems. We model linear polymer chains using atomistic bead-spring models. Some of these beads are defined as “sticky” and may form additional cross-links. Using Monte Carlo methods, computational load displacement curves are obtained and analysed. I will discuss how the density of sticky sites, their arrangement, topology and coordination influences the mechanical behavior of a single polymer chain or of a chain bundle. In particular, it will be shown that temperature and entropy reduce the efficacy of these bonds significantly, although the cross-links are relatively strong with a binding energy of approximately 50 kBT [1]. It will be discussed how the topology of formed cross-links influences the most basic mechanical parameters of the system like elastic modulus, work to fracture and strength. I will show that compared to non-cross-linked fibers the strength in chain bundles may even be reduced when cross-links are introduced in the system [2]. Finally, the influence of the coordination of cross-links on the mechanics of fibrous systems will be discussed. Motivated by metal coordination bonds that may form cross-links between more than two monomers, it will be shown that a higher coordination changes the mechanics of the system drastically [3]. Enhanced Beam-Theory Derived Shear Stress Distributions in Tramway Rails

Patricia Hasslinger*, Aleš Kurfürst**, Edgar Fischmeister***, Thomas Hammer****, Christian Hellmich*****, Stefan Scheiner******

*Institute for Mechanics of Materials and Structures, TU Wien - Vienna University of Technology, Vienna, Austria, **Institute for Mechanics of Materials and Structures, TU Wien - Vienna University of Technology, Vienna, Austria, ***Wiener Linien GmbH & Co KG, Vienna, Austria, ****Wiener Linien GmbH & Co KG, Vienna, Austria, *****Institute for Mechanics of Materials and Structures, TU Wien - Vienna University of Technology, Vienna, Austria, ******Institute for Mechanics of Materials and Structures, TU Wien - Vienna University of Technology, Vienna, Austria

ABSTRACT

In many urban areas, tramways are the backbone of the local public transport system imposing high requirements on its reliability. During service, rail fractures and material degradation due to wear or environmental influences are the main causes of disruptions. Rail fractures occur if the loads acting onto the rails induce stress states which exceed the strength of the steels the rails are made of. In the case of rail transport, these loads, resulting predominantly from the rail car axles, are not only extraordinary high, but also concentrated on small contact areas between the rail car wheels and the rails. In this study, the fracture tendency of tramway rails is investigated by employing a novel shear-compliant beam theory, considering normal and shear forces, bending moments as well as primary and secondary torsional moments. Our main interest lies in shear stress distributions throughout the cross sections of grooved rails. Interestingly, the locations of maximum shear stresses arising from discontinuities in shear forces, as encountered with abrupt changes in the embedment conditions, agree remarkably well with fracture patterns observed in real life. This marks a new level of advanced computational mechanics entering railway engineering.

Prediction of Thermoelastic Behavior of Porous Media Using a Multiscale Asymptotic Expansion Homogenization Method

Mohammad Hatami*, Alireza Sarvestani**, David Bayless***

*PhD Student, **Assistant Professor, ***Professor

ABSTRACT

Mineralogical compositions, such as shale, are modeled as multiphase porous materials with mechanical properties that are mainly influenced by mineral grains, pores, pore networks, and their permeability. Asymptotic expansion homogenization (AEH) is a multiscale computational methodology primarily used for determination of stress and deformation in heterogeneous materials. By decoupling the local (micro) and a global (macro) length scales, this method is proved to be a computationally efficient tool to evaluate the continuum field quantities in a localized region of interest. In this research, an AEH scheme is built into a finite element model to study the thermo-elasticity of heterogeneous porous media. A stochastic method based on Gaussian function distributions is used to generate realistic random microstructures within the matrix, with different porosities. Based on the proposed AEH method, homogenized material properties, namely thermal conductivity, Young's modulus, and thermal expansion coefficient of the porous media are determined. Consequently, the effect of pore size and porosity on distribution of stress and deformation in a cylindrical shale sample placed in a gas permeability chamber is studied. The effect of gas pressure gradient coupled with other microstructural variables on the evolution of stress and deformation at microscales are studied.

Modelling Selective Laser Melting with Focus on Optimizing the Scanning Path for Minimizing Final Distortions

Jesper Hattel*, Sankhya Mohanty**

*Technical University of Denmark, DTU, **Technical University of Denmark, DTU

ABSTRACT

Residual stresses and deformations continue to remain one of the primary challenges towards expanding the application of selective laser melting (SLM) as an industrial scale manufacturing process. The process continues to suffer from these challenges due to the localized heating, rapid cooling and high temperature gradients that occur during the process. To address these issues, numerical model based process optimization strategies for laser-scanning paths are presented and discussed. Various reduced order models simulating the thermal, mechanical and thermo-mechanical phenomena during SLM, which have been developed by combining commercial software with in-house codes, are demonstrated. A multilevel optimization strategy is adopted using a customized genetic algorithm developed for optimizing cellular scanning strategy for selective laser melting, with the objective of reducing residual stresses and deformations. The resulting thermo-mechanically optimized cellular scanning strategies are compared with standard scanning strategies and have been used to manufacture standard samples. The optimization results show how model-based process optimization can reduce the geometrical irregularities and ensure dimensional tolerances. Keywords: Additive Manufacturing, 3D printing, thermomechanical modelling, distortions, optimization

Abstract. The non-homogeneous boundary condition for the pressure Poisson partial differential equation in MPS are transformed to the source term of the pressure Poisson partial differential equation.

1 INTRODUCTION

When Koshizuka et al. [3] developed the Moving Particle Semi-implicit method, they computed pressure by solving the Poisson partial differential equation with the “homogeneous” Neumann boundary condition. Later, Asai [5] , Tamai [6] and other researchers solved the Poisson partial differential equation with the “non-homogeneous” Neumann boundary condition.

By the mathematics theory about partial differential equation, non-homogeneous boundary condition can be transformed to the source term of the partial differential equation by using Dirac delta functions [1].

In this presentation, the authors applies this mathematics theory to the problem how to compute pressure by solving the Poisson partial differential equation. The non-homogeneous Neumann boundary condition will be transformed to the source term of the Poisson partial differential equation with the homogeneous Neumann boundary condition. This source term corresponds to the particle number density feedback of the Moving Particle Semi-implicit method.

2. FLUID PARTICLES

Let $\Omega(t)$ be the liquid's fluid domain at time t. Let $\partial\Omega(t)$ be the boundary of the fluid domain $\Omega(t)$. The boundary $\partial\Omega(t)$ consists of the free surface $\partial\Omega(t)$_Dirichlet of the liquid and the wall $\partial\Omega$_Neumann of the waterway. That is

$$\partial\Omega(t) = \partial\Omega(t)\_\text{Dirichlet} \cup \partial\Omega\_\text{Neumann} \quad (1)$$

We assume that the wall of the waterway does not move and $\partial\Omega$_Neumann does not change as the time t goes on. .

For the position $\boldsymbol{r} = (r_x, r_y, r_z) \in \Omega(t)$ and the time t, let $\boldsymbol{a}(t,\boldsymbol{r})$ be the acceleration of the fluid particle $\boldsymbol{r}$, let $\boldsymbol{v}(t,\boldsymbol{r})$ be the velocity of the fluid particle $\boldsymbol{r}$,, let $P(t,\boldsymbol{r})$ be the pressure around the fluid particle $\boldsymbol{r}$, and let $\rho(t,\boldsymbol{r})$ be the mass density around the fluid particle $\boldsymbol{r}$. Let

$$\frac{\partial}{\partial \boldsymbol{r}} = \left(\frac{\partial}{\partial r_x}, \frac{\partial}{\partial r_y}, \frac{\partial}{\partial r_z} \right) \quad (2)$$

be the spatial partial differential operator. Then the Laplace partial differential operator (which is positive definite) is expressed as

$$(-1)\frac{\partial}{\partial \boldsymbol{r}} \cdot \frac{\partial}{\partial \boldsymbol{r}} = (-1)\frac{\partial}{\partial r_x}\frac{\partial}{\partial r_x} + (-1)\frac{\partial}{\partial r_y}\frac{\partial}{\partial r_y} + (-1)\frac{\partial}{\partial r_z}\frac{\partial}{\partial r_z} \quad (3)$$

3. NAVIER-STOKES PARTIAL DIFFERENTIAL EQUATION

The dynamics of the fluid particle $\boldsymbol{r}$ is governed by the following Navier-Stokes partial differential equation

$$\frac{D\boldsymbol{r}}{Dt} = \boldsymbol{v}(t,\boldsymbol{r}) \qquad \text{for} \quad \boldsymbol{r} \in \text{Int}\,\boldsymbol{\Omega}(t) \quad (4)$$

$$\rho\, \boldsymbol{a}(t,\boldsymbol{r}) = \rho \frac{D\boldsymbol{v}}{Dt} = (-1)\frac{\partial P}{\partial \boldsymbol{r}} + \mu \frac{\partial}{\partial \boldsymbol{r}} \cdot \frac{\partial}{\partial \boldsymbol{r}}\, \boldsymbol{v}(t,\boldsymbol{r}) + \rho\, \boldsymbol{g} \quad \text{for } \boldsymbol{r} \in \text{Int}\, \boldsymbol{\Omega}(t) \quad (5)$$

and the boundary conditions

$$0 = \boldsymbol{v}(t,\boldsymbol{r}) \quad \text{for } \boldsymbol{r} \in \boldsymbol{\partial\Omega}\text{\_Neumann} \quad (6)$$

$$0 = \boldsymbol{a}(t,\boldsymbol{r}) \quad \text{for } \boldsymbol{r} \in \boldsymbol{\partial\Omega}\text{\_Neumann} \quad (7)$$

$$0 = \boldsymbol{v}(t,\boldsymbol{r}) \cdot \boldsymbol{n}(\boldsymbol{r}) \quad \text{for } \boldsymbol{r} \in \boldsymbol{\partial\Omega}\text{\_Neumann} \quad (8)$$

$$0 = \boldsymbol{a}(t,\boldsymbol{r}) \cdot \boldsymbol{n}(\boldsymbol{r}) \quad \text{for } \boldsymbol{r} \in \boldsymbol{\partial\Omega}\text{\_Neumann} \quad (9)$$

Here, $\boldsymbol{g} = (0,\ 0,\ -9.81[\text{m/s}^2])$ is the gravity acceleration. $\boldsymbol{n}(\boldsymbol{r})$ is the "inner" normal vector at position $\boldsymbol{r} \in \partial\Omega$_Neumann .

Since we consider the case that the fluid's velocity is sufficiently smaller than the sound velocity, we assume the flow's incompressibility

$$\frac{\partial}{\partial \boldsymbol{r}} \cdot\, \boldsymbol{v}(t,\boldsymbol{r}) = 0 \qquad \text{for } \boldsymbol{r} \in \text{Int}\, \boldsymbol{\Omega}(t) \quad (10)$$

4. PRESSURE POISSON PARTIAL DIFFERENTIAL EQUATION AND BOUNDARY CONDITION

Applying $\partial/\partial \boldsymbol{r}$ to the both sides of the Navier-Stokes partial differential equation (5) and considering the incompressibility (10), one obtain the following Poisson partial differential equation

$$\rho \frac{\partial}{\partial \boldsymbol{r}} \cdot \boldsymbol{a}(t,\boldsymbol{r}) = (-1)\frac{\partial}{\partial \boldsymbol{r}} \cdot \frac{\partial}{\partial \boldsymbol{r}}\, P(t,\boldsymbol{r}) + 0 + 0 \quad \text{for } \boldsymbol{r} \in \text{Int}\, \boldsymbol{\Omega}(t) \quad (11)$$

id est

$$(-1)\frac{\partial}{\partial \boldsymbol{r}} \cdot \frac{\partial}{\partial \boldsymbol{r}}\, P(t,\boldsymbol{r}) = f(t,\boldsymbol{r}) = \rho \frac{\partial}{\partial \boldsymbol{r}} \cdot \boldsymbol{a}(t,\boldsymbol{r}) \quad \text{for } \boldsymbol{r} \in \text{Int}\, \boldsymbol{\Omega}(t) \quad (12)$$

Let $\boldsymbol{n}(\boldsymbol{q})$ be the "inner" normal vector at position $\boldsymbol{q} \in \partial\Omega$_Neumann . The spatial partial derivative along the "inner" normal vector and the spatial partial derivative along the "outer" normal vector may not equal. The spatial partial derivative along the "inner" normal vector can be computed by physical quantities in the fluid domain $\Omega(t)$, although the spatial partial derivative along the "outer" normal vector cannot be computed by physical quantities in the fluid domain $\Omega(t)$.

Taking the inner product between the inner normal vector $\boldsymbol{n}(\boldsymbol{q})$ and the both sides of the Navier-Stokes partial differential equation (5), one obtain the

Neumann boundary condition

$$\rho\, \boldsymbol{a}\cdot\boldsymbol{n} = (-1)\frac{\partial P}{\partial \boldsymbol{n}} + \left(\mu \frac{\partial}{\partial \boldsymbol{r}}\cdot\frac{\partial}{\partial \boldsymbol{r}}\, \boldsymbol{v}\right)\cdot\boldsymbol{n} + \boldsymbol{g}\cdot\boldsymbol{n} \quad \text{for } \boldsymbol{q}\in \partial\Omega\_\text{Neumann} \quad (13)$$

id est

$$\frac{\partial P(t,\boldsymbol{q})}{\partial \boldsymbol{n}(\boldsymbol{q})} = h(\boldsymbol{q}) = \boldsymbol{g}\cdot\boldsymbol{n} + (-1)\rho\, \boldsymbol{a}\cdot\boldsymbol{n} + \left(\mu \frac{\partial}{\partial \boldsymbol{r}}\cdot\frac{\partial}{\partial \boldsymbol{r}}\, \boldsymbol{v}\right)\cdot\boldsymbol{n} \quad (14)$$

$$= \boldsymbol{g}\cdot\boldsymbol{n} + 0 + 0 \quad (15)$$

because the boundary condition (8) and (9) at the wall $\partial\Omega\_\text{Neumann}$.

At time t and the position $\boldsymbol{q}\in\partial\Omega(t)\_\text{Dirichlet}$ on the free surface, the pressure satisfies the Dirichlet boundary condition

$$P(t,\boldsymbol{q}) = 0 \quad \text{for } \boldsymbol{q}\in\partial\Omega(t)\_\text{Dirichlet} \quad (16)$$

5. GREEN FUNCTION FOR HOMOGENEOUS BOUNDARY CONDITION

Let $K(\boldsymbol{r},\boldsymbol{q})$ be the Green function of the Poisson partial differential equation and the homogeneous boundary condition [2]. The Green function $K(\boldsymbol{r},\boldsymbol{q})$ satisfies the Poisson partial differential equation

$$\delta(\boldsymbol{r}-\boldsymbol{q}) = (-1)\frac{\partial}{\partial \boldsymbol{r}}\cdot\frac{\partial}{\partial \boldsymbol{r}}\, K(\boldsymbol{r},\boldsymbol{q}) \quad \text{for } \boldsymbol{r},\boldsymbol{q}\in \operatorname{Int}\Omega(t) \quad (17)$$

with the source term $\delta(\boldsymbol{r}-\boldsymbol{q})$, the homogeneous Neumann boundary condition

$$\frac{\partial}{\partial \boldsymbol{n}(\boldsymbol{r})}\, K(\boldsymbol{r},\boldsymbol{q}) = 0 \ \text{ for } \boldsymbol{r}\in\partial\Omega(t)\_\text{Neumann} \text{ for } \boldsymbol{q}\in \operatorname{Int}\Omega(t) \quad (18)$$

and the homogeneous Dirichlet boundary condition

$$K(\boldsymbol{r},\boldsymbol{q}) = 0 \quad \text{for } \boldsymbol{r}\in\partial\Omega(t)\_\text{Dirichlet} \text{ and for } \boldsymbol{q}\in \operatorname{Int}\Omega(t) \quad (19)$$

6. NON-HOMOGENEOUS BOUNDARY CONDITION IS TRANSFORMED TO THE SOURCE TERM OF THE POISSON PARTIAL DIFFERENTIAL EQUATION

The solution $P(\boldsymbol{r})$ of the pressure Poisson partial differential equation (12) and the boundary conditions (14) (16) is expressed by the following integral

$$P(t.\boldsymbol{r}) = \int_{\boldsymbol{q}\in\Omega(t)} K(\boldsymbol{r},\boldsymbol{q})\, f(t,\boldsymbol{q}) d\boldsymbol{q} + \int_{\boldsymbol{q}\in\partial\Omega_{\text{Nuemann}}} K(\boldsymbol{r},\boldsymbol{q})\, h(\boldsymbol{q})\, d\boldsymbol{\sigma}(\boldsymbol{q}) \quad (20)$$

Let $\boldsymbol{\delta}(\boldsymbol{q})$ be the delta function whose support is $\partial\Omega$_Neumann.

$$P(t,\boldsymbol{r}) = \int_{\boldsymbol{q}\in\Omega(t)} K(\boldsymbol{r},\boldsymbol{q})\, f(t,\boldsymbol{q})d\boldsymbol{q} + \int_{\boldsymbol{q}\in\Omega(t)} K(\boldsymbol{r},\boldsymbol{q})h(\boldsymbol{q})\,\boldsymbol{\delta}(\boldsymbol{q})\,d\boldsymbol{q} \quad (21)$$

$$= \int_{\boldsymbol{q}\in\Omega(t)} K(\boldsymbol{r},\boldsymbol{q})\big(\ f(t,\boldsymbol{q}) + h(\boldsymbol{q})\,\boldsymbol{\delta}(\boldsymbol{q})\ \big)d\boldsymbol{q} \quad (22)$$

Then the pressure $P(t,\boldsymbol{r})$ is also be computed by the following Poisson partial differential equation

$$(-1)\frac{\partial}{\partial \boldsymbol{r}}\cdot\frac{\partial}{\partial \boldsymbol{r}}\,P(t,\boldsymbol{r}) = f(t,\boldsymbol{r}) + h(\boldsymbol{r})\,\boldsymbol{\delta}(\boldsymbol{r}) \quad \text{for } \boldsymbol{r}\in \text{Int}\,\boldsymbol{\Omega}(t) \quad (23)$$

with the source term $f(t,\boldsymbol{r}) + h(\boldsymbol{r})\,\boldsymbol{\delta}(\boldsymbol{r})$ and the homogeneous B.C.

$$\frac{\partial P(t,\boldsymbol{q})}{\partial \boldsymbol{n}(\boldsymbol{q})} = 0 \quad \text{for } \boldsymbol{q}\in\partial\Omega\text{_Neumann} \quad (24)$$

$$P(\mathrm{t},\boldsymbol{q}) = 0 \quad \text{for } \boldsymbol{q}\in\partial\Omega(t)\text{_Dirichlet} \quad (25)$$

7. PARTICLE NUMBER DENSITY FEEDBACK IN MPS

Tanaka and Masunaga [4] computed the pressure by solving the following Poisson partial differential equation

$$\left(\frac{-1}{\rho_0}\right)\frac{\partial}{\partial \boldsymbol{r}}\cdot\frac{\partial}{\partial \boldsymbol{r}}\,P(t,\boldsymbol{r}) = (1-\alpha)\frac{\partial}{\partial \boldsymbol{r}}\cdot\frac{0-\boldsymbol{v}(t-\Delta t\,,\ \boldsymbol{r})}{\Delta t} + \alpha\,\frac{n(t\,,\ \boldsymbol{r})-n_0}{\Delta t\,\Delta t} \quad (26)$$

$$= (1-\alpha)\frac{\partial}{\partial \boldsymbol{r}}\cdot\frac{\boldsymbol{v}(t\,,\boldsymbol{r})-\boldsymbol{v}(t-\Delta t\,,\boldsymbol{r})}{\Delta t} + \alpha\,\frac{n(t\,,\boldsymbol{r})-n_0}{\Delta t\,\Delta t} \quad (27)$$

$$= (1-\alpha)\frac{\partial}{\partial \boldsymbol{r}}\cdot\boldsymbol{a}(t,\boldsymbol{r}) + \alpha\,\frac{n(t\,,\ \boldsymbol{r})-n_0}{\Delta t\,\Delta t} \quad \text{for } \boldsymbol{r}\in\text{Int}\,\boldsymbol{\Omega}(t) \quad (28)$$

with homogeneous boundary conditions. Here, $n(t,\boldsymbol{r})$ is the particle number density at time t, n_0 is the true value of the particle number density, ρ_0 is the true value of the mass density of the fluid, and $0 \le \alpha \le 1$ is the weight coefficient for the feedback of the particle number density.

By considering that the fluid particles always collides the bottom of the wall $\partial\Omega$_Neumann the waterway, the equation (23) corresponds to the equation (28).

8 CONCLUSIONS

The pressure Poisson partial differential equation with the non-homogeneous boundary condition is transformed to the pressure Poisson partial differential equation with homogeneous boundary condition whose source term is the mass density feedback which was introduced by Moving Particle Semi-implicit method .

ACKNOWLEDGEMENT

The authors would like to express their thanks to Prof. Yoshihiro SHIBATA (Waseda University) for discussing about the derivation for the Neumann boundary condition for the pressure Poisson partial differential equation. Also they would like to express their thanks to Dr. Tasuku TAMAI (The University of Tokyo) for discussing about the importance of the Neumann boundary condition for the pressure Poisson partial differential equation in Moving Particle Simulation [6].

ABSTRACT

Over the past 10 years there has been a resurgent interest in the development of novel metallic alloys, both as multiple principle component solid solution alloys, so-called high entropy alloys (HEA) as well as amorphous metallic glasses. Although a number of empirical rules have been proposed for the prediction of potential alloy compositions, calculating their stability and quantifying their properties of interest at operating temperatures from first principles represents a significant challenge. In fact, even high-throughput experimental studies struggle to effectively explore such large composition-processing-property parameter spaces efficiently. Here, I will discuss an approach that seeks to address the rational experimental exploration of such alloys by combining theory, experiment and data science. Our approach is to use insights from the literature, theory, and/or data mining to identify the regions of parameter space most likely to yield interesting materials. We then employ computationally guided high-throughput synthesis techniques to strategically probe composition and processing space. In situ synchrotron diffraction studies yield tens of thousands of data sets describing the evolution of the alloy phase and corrosion products. The data are evaluated using automated knowledge extraction techniques, enabling us to assess our experiments, update the models used to generate the initial lead materials, and plan the next material system to study. In this talk, I will emphasize our recent work using these techniques to investigate phase stability in metallic glasses.

Title: A Collision-Based Hybrid Method for Linear Transport

Cory Hauck*

*Oak Ridge National Laboratory

ABSTRACT

We present a hybrid method for simulating kinetic equations with multiscale phenomena in the context of linear transport. The method consists of (i) partitioning the kinetic equation into collisional and non-collisional components; (ii) applying a different numerical method to each component; and (iii) re- partitioning the kinetic distribution after each time step in the algorithm. Preliminary results show that, for a wide range of test problems, the combination of a low-order method for the collisional component and a high-order method for the non-collisional component provides a level of accuracy that is comparable to a uniform high- order treatment of the entire system. We also investigate the use of integral-deferred correction techniques to increase the temporal accuracy of the individual components of the hybrid method and assess the benefits in overall efficiency.

Homogenization and Design Optimization for a Periodic Heterogeneous Plate with Frame Structure under a Given Constraint

Michael Hauck*, Julia Orlik**, Stephan Wackerle***

*Fraunhofer ITWM, **Fraunhofer ITWM, ***Fraunhofer ITWM

ABSTRACT

The design optimization problems for heterogeneous elastic plates with frame structure as shown in [1] arise in many different applications, for instance in filters under local bending or analysis of textiles. We consider a plate with an in-plane periodic structure under a local point-bending moment or force. We employ basic homogenization techniques for linear periodic heterogeneous plates and pass to the anisotropic Kirchhoff-Love plate in the limit, where the effective bending coefficients were obtained from the auxiliary bending unit experiments on the periodicity cell by averaging of the local moments of outer-plane stresses. Since the plate structure is made of beam, we use the beam-FE method for solving the cell-problems. We homogenize the plate and then find an analytic solution under the local bending perturbation. Our further aim is to minimize the deflection caused by a localized load in the effective anisotropic plate. For that case we need to define a design space as in [2], which takes into account the constraint of anisotropy. We provide a particular example, where we can show how the design parameters influence the maximal plate deflection. References: [1] Hauck, M., Klar, A., & Orlik, J. (2017). VMS A Posteriori Error Estimation for the Incompressible NS Equations

Guillermo Hauke*, Diego Irisarri**

*EINA - Zaragoza, **EINA - Zaragoza

ABSTRACT

The genesis of stabilized methods was established in [1] from the standpoint of the variational multiscale theory (VMS). By splitting the solution into resolved and unresolved scales, it was shown that stabilized methods take into account an approximation of the unresolved scales into the finite element solution. Recent works have shown that these unresolved scales contain fairly accurate error information that can be exploited to formulate explicit a posteriori error estimators which are consistent with the assumptions inherent to stabilized methods [2,3]. In this presentation new highlights will be given about global and local a posteriori estimation for the incompressible Navier-Stokes equations using the VMS error time-scales. References: [1] T.J.R. A Review of VMS for A Posteriori Error Estimation

Guillermo Hauke*

*EINA - Zaragoza

ABSTRACT

The variational multiscale theory (VMS) was proposed in [1] to explain and unify various fundamental problems in computational mechanics including the origin of stabilized methods. By splitting the solution into resolved and unresolved scales, it was shown that stabilized methods take into account an approximation of the unresolved scales into the finite element solution. These unresolved scales contain important subgrid information, that has been used up for providing accurate turbulence models for LES [2]. Recent works have also shown that the unresolved scales can be used to formulate explicit and implicit a posteriori error estimators which are consistent with the assumptions inherent to stabilized methods [3]. In this presentation we will summarize the achievements of VMS and the error-time scales to estimate the numerical error and its potential to adapt the meshes. [1] T.J.R. Hughes, Multiscale phenomena: Green's functions, the Dirichlet-to-Neumann formulation, subgrid scale models, bubbles and the origins of stabilized methods. Comput. Meth. Appl. Mech. Engrg. 127, 387--401, (1995). [2] Y. Bazilevs, V.M. Calo, J.A. Cottrell, T.J.R. Hughes, A. Reali, G. Uncertainty Quantification in Finite Element Models: Application to Soft Tissue Biomechanics

Paul Hauseux*, Jack S. Hale**, Raphaël Bulle***, Franz Chouly****, Alexei Lozinski*****, Stéphane P.A. Bordas******

*University of Luxembourg, **University of Luxembourg, ***University of Luxembourg, ****Bourgogne Franche Comté University, *****Bourgogne Franche Comté University, ******University of Luxembourg and Cardiff University

ABSTRACT

We present probabilistic approaches aiming at the selection of the best constitutive model and to identify their parameters from experimental data. These parameters are always associated with some degree of uncertainty. It is therefore important to study how this statistical uncertainty in parameters propagates to a safety-critical quantity of interest in the output of a model. Efficient Monte Carlo methods based on variance reduction techniques (Sensitivity Derivatives Monte Carlo methods [Hauseux et al. 2017] and MultiLevel Monte Carlo [Giles 2015] methods) are employed to propagate this uncertainty for both random variables and random fields. Inverse and forward problems are strongly connected. In a bayesian setting [Matthies et al. 2017], developing methods that reduce the number of evaluations of the forward model to an absolute minimum to achieve convergence is crucial for tractable computations. Numerical results in the context of soft tissue biomechanics are presented and discussed.

A Plate Element Formulation for Modeling Progressive Damage and Residual Strength of Laminates

Devlin Hayduke*

*Materials Sciences Corporation

ABSTRACT

Advanced composite material systems are vital to the development of lightweight, multi-functional aerospace structures. In addition to reducing the weight of the structure, these material systems provide the ability to expand the function of the structure by tailoring stiffness and strength characteristics for numerous applications. Consequently, carbon fiber-reinforced epoxy structures have become very attractive for airframe applications. It is normally accepted that a limiting characteristic of laminated composite structures of this nature is the response of the impacted material to compressive loads, e.g. buckling. It is also well documented that delamination is the predominant damage mode in composite materials subjected to impact damage. Consequently, novel advanced composite material design and analysis approaches are sought to minimize the risk of damage from low-energy impacts resulting from operations and maintenance impact accidents. An analysis tool that contains novel mathematical/physical approaches for accurately assessing the residual compressive strength in impact-damaged composite structures is desired. In response to this need, a user element (UEL) subroutine for use with commercially available analysis codes has been developed by Materials Sciences Corporation. In particular, an enhanced plate formulation element that offers advantages in both the economy and reliability of computations has been realized. The formulation integrates a nonlinear material model to evaluate progressive damage and failure of composite materials on a ply-by-ply basis while incorporating a shear correction model that accurately predicts the nonlinear transverse response of impacted composite structures. A brief overview of the theoretical formulation of the element and embedded nonlinear material model will be provided. Followed by examples of standard characterization tests and the corresponding data reduction methodology required to determine model parameters for a commonly used intermediate modulus carbon fiber reinforced epoxy material system. In addition, an example of the residual strength predictions for a standard test specimen that exhibits progressive damage due to transverse shear will be reviewed. Finally, results of analysis models, e.g., dynamic and quasi-static, that were used to predict residual strength of an impacted laminated panel will be compared to experimental results.

Investigation of Fluid-Driven Fracture in Porous Medium Using Diffusive Phase-Field Fracture Approach

Bang He*, Pania Newell**, Mary Wheeler***

*The University of Utah, **The University of Utah, ***The University of Texas at Austin

ABSTRACT

The fluid-driven fracture exists in many porous mediums, including but not limited to, geological subsurface media, biological organs, chemical reactant, etc. The fracture in porous matrix is usually a primary concern, because it often relates to the failure of entire material system. Therefore, understating the mechanism of fluid-driven fracture in porous medium is an important task in many scientific and engineering applications. However, because of the complex coupled physics of the intertwining interaction among fluid flow, porous medium, and fracture propagation, as well as the stress singularity at the crack tip, it is usually challenging to numerically investigate it. Some recent works on the phase-field modeling have constructed the generalized free energy equation for saturated porous medium by taking the pressure term and phase-field free energy into account, where the phase-field method is extended to the fully coupled fluid-driven fracture problems in porous medium. With this method, it is feasible for us to take a closer look at the essential characteristics of the fluid-driven fracture in porous medium and circumvent the discontinuity problem in numerical simulation. Therefore, we conducted two comprehensive investigation of the fluid-driven fracture in porous medium based on the penny crack model, considering that penny crack is massively investigated in published literature and there are lots of data available to validate our numerical result through comparison. The first part will focus on the influence of fluid injection pressure on fracture growth pattern for a given porous medium. With this work, the relation between fracture propagation and fluid injection can be established. Moreover, we anticipate that the underlined porosity (e.g. shape, size, and distribution) will also impact the fracture growth. Therefore, aside from the injection pressure-fracture relation, we will also present an endeavor to explore the porosity and pore size effect on fracture growth by using the multi-scale phase-field modeling method for fractured porous structure. In this study, the contribution of porosity and pore size to fracture will be studied by considering their continuous effect on the permeability and Biot's coefficient. Furthermore, at the pore-scale, the fracture growth along the variation of porosity and pore size will also be examined by modeling the pore with micro element and carrying over the micro element response to macro models. Through this investigation, we can extend our understanding on how

An Evaluation Approach of Dynamic Brittle Fracture Using Limited Sensor Data

Jingjing He*, Yibin Zhou**, Yongxiang Wang***, Haim Waisman****, Rilin Shen*****

*Beihang University, **Beihang University, ***Columbia University, ****Columbia University, *****Harbin Institute of Technology

ABSTRACT

The prevention of fracture-induced failure is a major challenge in engineering designs, as a consequence, a wide variety of numerical simulations of fracture processes have been studied over decades. In this work, we propose a simulation approach for brittle fracture to the dynamic case combined with dynamic responses reconstruction method and phase-field model. In contrast to discrete descriptions of fracture, phase-field descriptions do not require numerical tracking of discontinuities in the displacement field. The fracture surface is approximated by a field, which smoothes the boundary of the crack over a small region. The evolution of fracture surfaces follows from the solution of a coupled system of partial differential equations, which greatly reduces implementation complexity. The previous work named as REMD (reconstruction based on empirical mode decomposition) is extended to accurately obtain the structural displacement responses in time domain. One of the advantages of the REMD is to provide accurate dynamic response information for fracture crack simulation using sparse and remote strain gauges installed in the structure. For the mode shape information will change as the stiffness of cracked elements decrease in the fracture process, we present a step calculation scheme to update the exact mode shape included crack evolution information. Then, the behavior of the dynamic model is studied by performing a number of numerical cases. These cases show that the combination of the phase-field model and REMD provides an effective method for simulating fracture process in two dimensions.

A Decomposed Subspace Reduction for Fracture Mechanics Based on ISBFM Galerkin Meshfree Method

Qizhi He*, J. S. Chen**, Camille Marodon***

*University of California, San Diego, **University of California, San Diego, ***OptimaRH Consulting

ABSTRACT

Repeated simulations of fracture in materials under various conditions are important in many applications but are computationally unaffordable. A decomposed subspace reduction (DSR) method is proposed for fracture mechanics modeled by a Galerkin meshfree method, where the meshfree approximation is based on a smooth reproducing kernel approximation enriched by non-smooth near-tip basis functions. The Galerkin formulation is formulated via the integrated singular basis function method (ISBFM) [1, 2] to avoid the need of high-order quadrature scheme for domain integration near the crack tip, and consequently yields a sparser discrete system for effective model order reduction (MOR) procedures. The DSR method is proposed for the ISBFM discrete system, such that the low-rank representation of the smooth subspace is obtained while the non-smooth subspace is optimally preserved. Compared with the standard model reduction based on a modal projection, DSR better represents the singularity and discontinuity properties of fracture problem in its low-dimensional reduced-order approximation. Numerical examples are given to validate the effectiveness of the proposed MOR method for fracture mechanics. References [1] Georgiou, G. C., Olson L, Smyrlis Y. Adaptive Reduction of the Dimensionality of Multiscale Models in Solid Mechanics and Structural Dynamics

Wanli He*, Charbel Farhat**

*Stanford University, **Stanford University

ABSTRACT

Heterogeneous materials are often encountered in solid mechanics and structural dynamics problems. The brute force Finite Element (FE) solution of such problems usually requires extremely fine meshes and leads to prohibitively expensive numerical simulations. For this reason, alternative approaches such as the multiscale FE2 have been developed. Typically, these assume that the material configuration is homogeneous at the macroscale but heterogeneous at the smallest represented scale, and couple the sequence of scales using localization and homogenization procedures. For many problems however, they remain computationally unaffordable as at each but the finest scale, they require the solution of a unit cell problem at each quadrature point of the associated FE mesh. For this reason, a model reduction framework was recently presented in [1] for dramatically accelerating the solution of nonlinear dynamic multiscale problems. In this framework, the dimensionality of the governing equations is reduced using the POD method, and computational efficiency is achieved for the evaluation of the nonlinear reduced-order terms using the Energy Conserving Sampling and Weighting method. Training is performed in two steps. First, a microscale hyper reduced-order model is constructed in-situ in order to achieve significant speedups even in non-parametric settings. Next, a classical offline-online training approach is performed to build a parametric hyper reduced-order macroscale model. A notable feature of this approach is the minimization, at the macroscale level, of the cost of the training using the in-situ hyper reduced-order microscale model to accelerate snapshot acquisition. A weak spot however is the in-situ training itself which, for sufficiently large macroscale models, requires an adaptive reduction process to keep the global ROB accurate and economical at all times. This talk will present such an adaptive process based on the concept of a database of local ROBs that is constructed and updated on-the-fly. This process treats the deformation gradient as a vector parameter domain, which enables it to locate each unit cell problem in the database and assign to it online the most appropriate local ROB. Its accuracy is optimized by collecting new snapshots as needed and updating accordingly the local ROBs. The resulting adaptive nonlinear model reduction framework is illustrated with the fast solution of several nonlinear dynamic multiscale problems. 1. M. J. Zahr, P. Avery, and C. Farhat, A Multilevel Projection-based Model Order Reduction Framework for Nonlinear Dynamic Multiscale Problems in Structural and Solid Mechanics, International Journal for Numerical Methods in Engineering, Vol. 112, pp. 885-881 (2017)

Beam Damage Localization Using Indirectly Identified Mode Shapes

Wen-Yu He*, Jian He**, Wei-Xin Ren***, Songye Zhu****

*Hefei University of Technology, **Hefei University of Technology, ***Hefei University of Technology, ****The Hong Kong Polytechnic University

ABSTRACT

This paper presents a damage localization method for beam structures by using the indirectly identified mode shapes without reference data. Mode shapes with high spatial resolution in a damaged state is extracted from the moving vehicle response via Hilbert transform (HT). To avoid the low anti-noise ability of the central difference method, regional mode shape curvature (RMSC) in the damaged state is defined to replace the traditional mode shape curvature. Subsequently the RMSC in an undamaged state is estimated by using the RMSC in a damaged state and the polynomial approximation that assumes RMSC in an undamaged state has smooth surface. Finally the RMSC change is used to localize damage in beam structures. Numerical studies are carried out to investigate the feasibility and efficiency of the proposed damage localization index (DLI). The results indicate that the proposed method can effectively overcome the disadvantages of traditional mode shape based damage localization methods , such as the requirement for high spatial resolution and reference mode shapes, and the central difference method induced low anti-noise ability.

Numerical Simulation for the Fracture Behaviour of Carbon Nanotubes

Xiaoqiao He*

*City University of Hong Kong

ABSTRACT

An atomic-based cellular automata algorithm (ACAA) is presented for the atomic-scale simulation of carbón nanotubes (CNTs). The ACAA employs the inter-atomic potential to account for multi-body interactions. Thus, the ACAA method is as accurate as the molecular dynamic (MD) method and much faster than MD simulations. The stress-strain response from elastic deformation to fracture of CNTs is simulated by using the ACAA method. The effect of a vacancy defect is examined on the tension characteristic of CNTs. The numerical results show that the ACAA is a effective method for the simulation of large system of CNTs.

The Effect of Marangoni Instabilities on Horizontal Ribbon Growth

Brian Helenbrook*

*Clarkson University

ABSTRACT

An arbitrary-Lagrangian-Eulerian hp finite element is used to study the dynamics of single-crystal horizontal ribbon growth of silicon. Solidification kinetics are included to model the non-isotropic growth of solid silicon. This study focuses on the fluid dynamics of the process in particular examining how Marangoni flows affect the final grown crystal. It is shown that depending on the chosen magnitude of the derivative of surface tension coefficient with temperature, marangoni stresses can cause a chaotic flow to develop. This flow leads to fluctuations in the free-surface height, which in turn create irregularities on the surface of the grown crystal. The amplitude and wavelength of the irregularities predicted by the model are compared to those seen in experiments performed at Applied Materials using the floating silicon method (a variant of horizontal ribbon growth).

Fast, Robust and Portable Implementations of Complex Mechanical Behaviours with the MFront Code Generator

Thomas Helfer*

*CEA, DEN, DEC, SESC

ABSTRACT

The PLEIADES software environment is devoted to the thermomechanical simulation of nuclear fuel elements behaviour under irradiation. This platform is co-developed in the framework of a research cooperative program between Électricité de France (EDF), AREVA and the French Atomic Energy Commission (CEA). Within this plateform, a unified software environment for capitalisation of material knowledge has been developed and released as an open-source project: the MFront code generator [2,3]. This code generator provides several high level domain specific languages that allow the user to express the constitutive equations in a form closed to their mathematical expression. Those domain specific languages use a mathematical library based on advanced programming techniques provided by the C++ language (template meta-programming, static polymorphism, expression templates, loop unrolling, etc..) which allow the compiler to highly optimize the generated code. This talk will focus on mechanical behaviours which are by essence complex and may have significant impact on the numerical performances of mechanical simulations. MFront users can describe all kinds of mechanical phenomena, such as viscoplasticity, plasticity and damage, for various types of mechanical behaviour (small strain or finite strain behaviour, cohesive zone models). MFront provides various interfaces to finite element solvers which allow the same implementation to be used in many finite element solvers, such as: Abaqus/Standard and Abaqus/Explicit, Ansys APL, CalculiX, Code_Aster, Cast3M, etc. Several benchmarks show that the generated mechanical behaviours are computationally efficient and have performances on par with native build-in implementations in Code_Aster, Cast3M, Abaqus/Standard, etc. This talk will provide: - an overview of the MFront code generator. - an example of the implementation of complex plastic behaviour at finite strain with an implicit scheme and the impact of the algorithms used to solve the implicit system on the robustness and numerical performances: those algorithms range from simple physically motivated modifications to the standard Newton-Raphson algorithm to advanced trust-region algorithms (Powell DogLeg, Levenberg-Marquart). ABSTRACT

Introduction FEM based prediction of hip fracture risk has in the past focused on the sensitivity of quasi-static femoral strength as a fracture risk indicator. The load that the femur is subjected to as a result of impact, which is the cause of most hip fractures, has sparsely been investigated. This study aimed to develop a high throughput pipeline for generating biofidelic FEMs that simulate impact loading resulting from sideways falling and assess their fracture classification accuracy. Methods Whole pelvic FEMs were generated from baseline CT scans for 254 females from the AGES-Reykjavik cohort. The femur on the impacted side was segmented from the CT data and corresponding FEM generated with heterogeneous, visco-plastic material properties mapped to it [1]. Models of soft tissue and other skeletal structures, not fully visible in the CT data, were generated with a combination of morphing and statistical shape modelling techniques. The FEMs were subject to sideways fall impact at 3 m/s. Fragility ratio (FR) was defined as the ratio between peak forces of paired biofidelic models, one with fully elastic and the other with non-linear material properties for the proximal femur. An expected end-point value (EEV) was defined as the FR weighted by the probability of falling assessed based on self-reported fall frequency at baseline. Bone tissue tensile damage and change in maximum volumetric strain (?MVS) were also assessed based on the FEM results. Fracture classification was quantified in terms of area under the receiver-operator curve (AUC). Results Age-adjusted AUC was highest for ?MVS (0.72), followed by FR (0.71), aBMD (0.70), and EEV (0.68). Partial-AUC corresponding to an osteoporotic threshold (aBMD of 0.57g/cm3) was highest for FR (0.043), followed by EEV (0.042), ?MVS (0.033), and aBMD (0.028). Maximum elastic femur force was correlated with femoral head radius, pelvis width, and soft tissue thickness (R2=0.79; RMSE=0.46 kN; p<0.005). Discussion The marginal improvement in FE-based AUC values compared to aBMD was similar to previous studies [2], however larger differences were observed for partial-AUC. The addition of fall frequency information did not significantly improve the sensitivity of hip fracture classification, suggesting that an improved assessment of fall probability is necessary for accurately identifying individuals predisposed to fracture. A novel estimate of peak femoral impact force as a function of subject biometrics provides valuable information for future studies simulating subject-specific impact loads. Multi-Scale Fracture Mechanics Approach to Simulate Crack Propagation in Repaired Sensitized Aluminum

Bozhi Heng*, Stephanie TerMaath**

*University of Tennessee, Knoxville, **University of Tennessee

ABSTRACT

Stress corrosion cracking (SCC) is one of the main failure modes of Al-Mg (5xxx series) alloys used in marine structures. The precipitation of Al2Mg3 ?-phase along grain boundaries takes place when Al-Mg alloys are exposed to elevated temperature over a prolonged time, which is defined as sensitization. The combination of marine environment and sensitization makes the alloys more susceptible to SCC due to the dissolution of the ?-phase in salt water. Fiber reinforced composite patches have been demonstrated as an effective approach to prevent and slow crack growth in ship structures. Characterization of crack repair performance will allow for use of composite patches as an alternative to traditional repair techniques as a permanent repair. The goal of this research is to develop high-fidelity multi-scale computational models to predict and investigate crack growth in sensitized aluminum repaired with composite patches. The main challenge of this research is the lack of conclusive experimental data and the current incomplete knowledge of the complex mechanism for SCC. Therefore, the main objective is to develop mathematical models to describe the mechanisms of crack growth in sensitized aluminum through experimentation and multi-scale modeling. Then the mathematical models will be applied to investigate the effects of composite patches on crack propagation in sensitized aluminum. The greatest advantage of the proposed multi-scale modeling is its ability to cover micro factors of material microstructure in SCC such as ?-phase distribution and grain orientation. However, this makes it difficult to homogenize models from a low-level scale to a high-level scale model. A developed probabilistic approach will be used for the homogenization process. Multiple cracks and branching crack growth is another reason for the complication of SCC analysis. A 3D model based on extended finite element method (XFEM) will be developed to simulate stress corrosion crack propagation with complex crack surfaces and crack paths.

Discretization of Weak and Strong Discontinuities in Non-Conformal Meshes

Paul Hennig*, Arne Claus Hansen-Dörr**, Markus Kästner***

*TU Dresden, Germany, **TU Dresden, Germany, ***TU Dresden, Germany

ABSTRACT

In the numerical analysis of heterogeneous materials, weak and strong discontinuities arise in the field variables due to rapidly changing mechanical properties at material interfaces or due to propagation of cracks if a specific failure load is exceeded. Details about the local topology of heterogeneous microstructures are typically taken from imaging methods or are given in terms of random distributions. To reduce the time for costly meshing processes, different non-standard discretization techniques have been developed to discretize these heterogeneities in non-conforming meshes. These include polygonal or extended FEM, the hp-d-adaptive finite cell method, or its hp-adaptive B-spline version [1]. While good convergence rates can be achieved for the latter two, stress oscillations may occur because sharp material interfaces are modeled in terms of a continuous basis. Here, we incorporate material interfaces into a non-conforming discretization using a regularized interface representation. Adaptive, local h-refinement based on THB-splines [2] is applied to provide an hr-adaptive refinement strategy, where element size h and regularization length r are reduced simultaneously. In combination with specific homogenization assumptions across the interface, good convergence rates and local stresses are obtained. To account for local damage and failure, the modeling of the heterogeneous material structure is extended by a phase-field model for bulk and interface cracks. In this way, the cumbersome topological updates of the analysis mesh to track the crack path, are avoided. Crack initiation and propagation is controlled by solving an additional scalar field problem that is coupled to the mechanical one [3]. To model interface failure between two materials we combine the phase field approach with a local reduction of the critical fracture energy in the area of the regularized material interface. The method considers possible interactions between the regularization of the interface and the phase-field and ensures crack propagation with the experimentally observed fracture toughness of the interface. Finally we demonstrate the proposed modeling approach in numerical examples for crack propagation in heterogeneous materials using non-conformal meshes. [1] D. Schillinger and E. Rank. Polymorphic Uncertainty Quantifciation for Stability Analysis of Fluid Saturated Soil and Earth Structures

Carla Henning*, Tim Ricken**

*University of Stuttgart, **University of Stuttgart

ABSTRACT

Nowadays, numerical simulations enable the description of mechanical problems in many application fields, e.g. in soil or solid mechanics. During the process of physical and computational modelling, a lot of theoretical model approaches and geometrical approximations are sources of errors. These can be distinguished into aleatoric (e.g. model parameters) and epistemic (e.g. numerical approximation) uncertainties. In order to get access to a risk assessment, these uncertainties and errors must be captured and quantified. In the framework of the priority program SPP 1886 of the DFG, in the present subproject (sp12) the focus is driven on quantification and assessment of polymorphic uncertainties in computational simulations of earth structures, especially for fluid-saturated soils. To describe the strongly coupled and non-linear solid-fluid response behavior, the theory of porous media (TPM) will be used [1]. To capture the impacts of different uncertainties on computational results, two promising approaches of analytical and stochastic sensitivity analysis will enhance the deterministic structural analysis [2, 3]. A simple consolidation problem already provided a high sensitivity in the computational results towards variation of material parameters and initial values. The variational sensitivities are used as a tool for optimization procedures and capture the impact of different parameters as continuous functions. An advantage is the accurate approximation of the solution space and the efficient computation time as well as the consistent and simultaneous development of the TPM model and its sensitivity expressions. A disadvantage lies in the complex analytical derivation and algorithmic implementation. In contrast to this access, the probabilistic sensitivity analysis from the field of statistics provides methods that indeed are combined with high computational costs, but have a great applicability and comparably low realisation effort. The overall objective is to figure out the respective strengths to develop more efficient methods and tools for the reliable and economic sizing of earth structures in the long-run. [1] W. Appropriate Inlet Boundary Conditions for Scale-Resolving Simulations of Turbomachinery Configurations

Florian Herbst*, Christoph Mueller-Schindewolffs**, Felix Schwarzbach***, Mark Ziesse****, Christoph Bode*****

*Institute of Turbomachinery and Fluid Dynamics, Leibniz Universitaet Hannover, Germany, **Institute of Turbomachinery and Fluid Dynamics, Leibniz Universitaet Hannover, Germany, ***Institute of Turbomachinery and Fluid Dynamics, Leibniz Universitaet Hannover, Germany, ****Institute of Turbomachinery and Fluid Dynamics, Leibniz Universitaet Hannover, Germany, *****Institute of Jet Propulsion and Turbomachinery, University of Braunschweig, Germany

ABSTRACT

Turbomachinery designer e.g. of jet engines constantly strive for maximizing the machine's power-to-weight ratio and efficiency, reducing noise emissions, and ensuring structural health. Achieving these objectives requires a thorough understanding of the flow physics as well as a precise prediction of the machine's characteristics in the design process. Turbomachinery flows cover a wide range of Reynolds and Mach numbers ranging from incompressible to compressible flow, incorporating laminar, transitional, and fully turbulent boundary layers. These effects as well as three-dimensional vortical flow structures, periodic-unsteady wake interactions, and multistage flow effects interact and determine the machine's characteristics. In the design process reduced-order models (e.g. RANS methods) of such flows are and will be for some time prime due to their computational efficiency. However, scale-resolving methods provide a powerful tool for the further development of reduced-order models as they provide spatially and temporal highly-resolved insight into these complex flow physics of realistic configurations. Against this background and with this motivation the authors applied and developed scale-resolving methods for complex turbomachinery applications in recent years [1,2]. Basis is an implicit finite-volume approach providing second order accuracy in time and space which has been applied either for LES (implicit and explicit modeling) or for hybrid computations. The current presentation focusses on the prescription of exact inflow conditions typical for turbomachinery configurations by means of a LES of a low-pressure turbine cascade. Those inflow conditions can either be generated by resource-intensive precursor simulations of three-dimensional periodic boxes or by synthetic boundary conditions, whereas the latter are cheaper and much more flexible. A modified synthetic-eddy-method will be presented which suits the demands and specifications of the application to turbomachinery. The approach provides interfaces for the prescription of steady and unsteady shear-layers, such as wakes, by temporally changing velocities, Reynolds-stresses, and turbulent length-scales. Furthermore, it will be extended to compressible flows by adding a mechanism to uncouple acoustic waves. The precision of the method will be shown by verification and experimental validation. Moreover, the relevance of such a flexible inlet boundary condition method for accurately simulating turbomachinery configurations with scale-resolving methods will be demonstrated.

Elastic and Dynamic Properties of Membrane Phase-field Models: the Viscosity of Blood and the Bending Rigidity of Red Blood Cells

Aurora Hernandez-Machado*

*University of Barcelona, Spain

ABSTRACT

Phase-field models have been extensively used to study interfacial phenomena, from solidification to vesicle dynamics. We will analyze a phase-field model that captures the relevant physical features that characterize biological membranes [1]. We will show that the Helfrich theory of elasticity of membranes can be applied to phase-field models, allowing to derive the expressions of the stress tensor, lateral stress profile and elastic moduli. We will discuss the relevance and interpretations of these magnitudes from a phase-field perspective. Taking the sharp-interface limit we will show that the membrane macroscopic equilibrium equation can be derived from the equilibrium condition of the phase-field interface. As an application, we will study a dynamic phase-field model that describes the behavior of red blood cell membranes [2]. The rheological properties of blood depend highly on the concentration and membrane elasticity of its red blood cells. These properties affect the viscosity of blood, as well as, its non-linear rheological (shear thinning) behavior. In some cases these effects are related to diseases, such as typical anemia or alpha-thalassemia. By mean of the analysis of the front advancement of blood in a microchannel, we will determine experimentally the viscosity of different samples of blood and we will relate the viscosity with the bending rigidity of its red blood cells. IDENTIFICATION OF DAMAGE IN FRAMES BASED ON THE CURVATURE MATRIX OF THE FRF.

JUAN C. HERRERA

Civil & Industrial Engineering Department
Faculty of Engineering
Pontificia Universidad Javeriana
Calle 18 No. 118-250, Cali, Colombia
E-mail:juancherrera@javerianacali.edu.co

Key words: damage identification, FRF, Timoshenko beam, structural health monitoring.

Summary. In this paper a method for damage identification in frame structures based on the curvature-matrix of the Frequency Response Function (FRF) is proposed. Two new indices to predict the damage location and to estimate the severity of the damage in a structure are formulated. To evaluate the effectiveness of the method, numerical simulations are performed in different damage scenarios simulated in a one-story, one-bay frame using the classic Timoshenko beam theory. The structural damage is simulated by reducing the shear and flexural stiffness of selected elements of the frame using Finite Element modelling. The FRF for the undamaged and damaged frame is obtained with the frequencies and mode shapes of the lower modes and the curvature of the FRF is numerically calculated by using a centered finite-difference based on the Taylor series expansion. The results indicate that the proposed method can localize and estimate the damage severity in simple frames.

1 INTRODUCTION

The structural condition assessment of existing civil infrastructures such as buildings and highway bridges is decisive to prevent probable catastrophic events and for planning the potential investments in repair, rehabilitation of this critical infrastructure. Structural damage identification through changes in dynamic characteristics, provide a global way to evaluate the structural condition. When damage occurs in a structure there is a change in one or more of its dynamic properties and these changes in the stiffness or flexibility of structure will cause changes in the modal properties.

In the last two decades a variety of methods based on Frequency Response Function (FRF) data have been proposed in the technical literature[1-4]. The use of FRFs for damage detection have definite advantages over the traditional methods using modal analysis data[5]. One significant advantage lies in the fact that FRF data provide abundant information on the dynamic behavior of a structure. Aditionally, the FRFs are less contaminated because they are directly measured from structures.

In this paper, a methodology for structural damage identification based on the FRF-Curvature is formulated. First, the concept of FRF-Curvature matrix is formulated. Next, two new damage indices based on the variations of this matrix over the structure are proposed. The damage indices are conceived to indicate the damage location and to estimate the severity of the damage in a structure directly from the measured FRF-Receptance. Finally, numerical simulations are performed to evaluate the effectiveness of the proposed damage indices to localize and quantify the severity of damage in a one-story, one-bay frame.

2 THE FREQUENCY RESPONSE FUNCTION

The general mathematical representation of a single degree of freedom (SDOF) system can be expressed by

$$m\ddot{x}(t) + c\dot{x}(t) + k\dot{x}(t) = F(t) \tag{1}$$

Assuming that the forcing function is harmonic of the form $F(t)=Fo^{ei\Omega t}$ and the damping is linear and viscous, the Frequency Response Function (FRF) can be defined by

$$H(\Omega) = \frac{1}{1-\left(\frac{\Omega}{\omega_n}\right)^2 + i2\xi\left(\frac{\Omega}{\omega_n}\right)} \tag{2}$$

where ωn and ξ are, respectively, the natural frequency and the damping ratio.

For multiple degree of freedom (MDOF) systems with classic damping, the Frequency Response Function (FRF) between the degrees of freedom *r* and *s* is defined as

$$H_{rs}(\Omega) = \sum_{j=1}^{n} \frac{\phi_{rj}\phi_{sj}}{\omega_j^2 - \Omega^2 + 2\xi_j\omega_j\Omega i} \tag{3}$$

where, ϕ_{ij} is the row "*i*" of the vibration mode "*j*"; ω_j y ξ_j are the natural frequency and the damping ratio of the "*j*" mode, respectively.

$H_{rs}(\Omega)$ is the response of the DOF *r* due to a single harmonic force excitation of unit amplitude applied at the DOF *s*. This particular FRF where the response or output is described in terms of the displacement and the input is a force is known as the Receptance function.

3 FORMULATION

In this work, a damage index based on the FRF-Curvature matrix is proposed. The index was conceived to predict the damage location and to estimate the severity of the damage in a structure directly from the measured FRF-Receptance. The damage indices are based on the change of the FRF-Curvature at the elements of the structure for a given excitation frequency.

The functions $H_{rs}(\Omega)$ defined by the Equation (3) can be arranged in matrix form. This leads to a Receptance Matrix defined as

$$[H(\Omega)]=\begin{bmatrix} H_{11} & H_{12} & \cdots & H_{1n} \\ H_{21} & H_{22} & \cdots & H_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ H_{n1} & H_{n2} & \cdots & H_{nn} \end{bmatrix} \tag{4}$$

The curvature matrix of the FRF-Receptance $[H''(\Omega)]$ is defined as:

$$[H''(\Omega)]=\begin{bmatrix} H''_{11} & H''_{12} & \cdots & H''_{1n} \\ H''_{21} & H''_{22} & \cdots & H''_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ H''_{n1} & H''_{n2} & \cdots & H''_{nn} \end{bmatrix} \tag{5}$$

The matrix for damage identification based on the Receptance curvature, is defined by

$$[\Theta]_{nxn}=[H''(\Omega)]_{nxp}[H''(\Omega)]^{T}_{pxn} \tag{6}$$

where,
$[H''(\Omega)]$: curvature matrix of the FRF-*Receptance* for a frequency Ω.
n: number of points where the FRF is obtained
p: number of points where the input force is applied.

If the input force is applied at a single point "*k*", the diagonal of $[\Theta]$ is defined as

$$\{\theta\}=\{(H''_{1,k})^2 \quad (H''_{2,k})^2 \quad \cdots \quad (H''_{n,k})^2\} \tag{7}$$

The Receptance-curvature for each frequency can be calculated numerically by using a central finite-divided difference based on an expansion of the Taylor series. For the Receptance FRF measured at location *j* due to a excitation force at position *k*, the curvature of the Receptance $H_{j,k}(\Omega)$ can be calculated by:

$$H''_{jk}(\Omega)=\frac{|H_{j+1,k}(\Omega)|-2|H_{j,k}(\Omega)|+|H_{j-1,k}(\Omega)|}{h^2} \tag{8}$$

where *h* is the distance between two consecutive measurement points: *(j)* and *(j+1)*.

For the damaged structure, the FRF curvature matrix is defined by

$$\left[\Theta_*\right]_{nxn} = \left[H''_*(\Omega)\right]_{nxp}\left[H''_*(\Omega)\right]^T_{pxn} \tag{9}$$

where $H''_*(\Omega)$ is the curvature of the FRF-*Receptance* for the damaged structure.

If the input force is applied at a point "*k*", the diagonal of $\left[\Theta_*\right]$ is defined as

$$\{\theta_*\} = \left\{(H''_{*1,k})^2 \quad (H''_{*2,k})^2 \quad \cdots \quad (H''_{*n,k})^2\right\} \tag{10}$$

In terms of the FRF curvature matrices, the index for damage location expresses the relationship between the states of a structure element with damage and without damage, defined by:

$$\{\chi\} = \{\theta_*\}./\{\theta\} \tag{11}$$

In the Equation (11) the symbol (./) is used to indicate that the division of the vectors is done element by element.

The proposed damage severity index is defined by

$$\{\Gamma\} = \eta\left[1 - \{\varphi\}./\{\varphi_*\}\right] \tag{12}$$

where,

$$\eta = \frac{\sum_{i=1}^{n} H''_{ik}}{\sum_{i=1}^{n} H''_{*i,k}} \tag{13}$$

After the damage index Γ_j is computed, the value of the indicator is normalized according to the rule formulated by Kim and Stubbs[6]:

$$Z_j = \frac{\Gamma_j - \mu}{\sigma} \tag{14}$$

where μ and σ are, respectively, the mean value and the standard deviation of the damage index Γ_j.

The damage is assigned to the elements by using a statistical-pattern-recognition technique that utilizes hypothesis testing[6]: The null hypothesis, referred to as H_0, corresponds to the structure *not* damaged at the element *j* and the alternate hypothesis, denoted as H_1, means that the structure *is* damaged at the element *j*. To assign damage to a specific location, the following decision rule is used: (a) select H_0 if $Zj < 1{,}9$ or (b) select the alternate H_1 if $Zj \geq 1{,}9$. This test corresponds to a confidence level of 97 %.

4 NUMERICAL SIMUATIONS

To demonstrate the effectiveness of the proposed damage indices to locate and estimate the structural damage, the one-storey frame shown in Figure 1 is considered. Four damage scenarios are analyzed. The FRF and the FRF-curvature of the damaged and undamaged structures were generated numerically. The FRF-curvature was obtained numerically with Equation (8).

The following dimensions and material properties are used for the frame: span length L= 2.5 m, height of the frame H=2.5 m, height of the cross section h=0.125 m, width of the cross section b= 0.05 m, elastic modulus E = 200000 MPa and mass density ρ= 20.21 kg/m3. For the numerical simulation the beam was divided into 20 finite elements of equal length. Four damage scenarios were studied and are listed in Table 1. The structural damage is simulated by reducing the flexural stiffness (*EI*) and the shear stiffness (*GA*) of an element near the beam's mid-span.

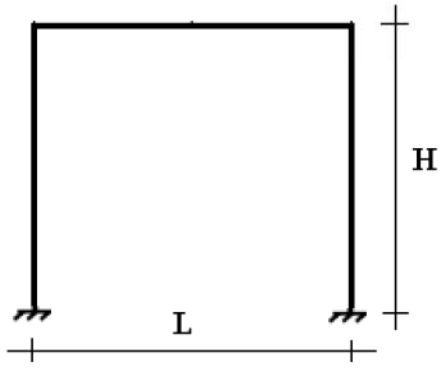

Figure 1. One-bay frame.

Damage scenario	Location	E,G reduction (%)
D1	0.5L	50
D2	0.5L	40
D3	0.5L	30
D4	0.5L	25

Table 1. Damage scenarios.

To calculate the proposed indices, the values of the Receptance-FRF were obtained at 19 locations equally spaced along the longitudinal axis of the beam. The Receptance-FRF was calculated with Equation (3) for the first three mode shapes and was assumed that the modal damping ratio ξ_j was constant for all the modes and equal to 0.05. Using the values of the Receptance FRF, the FRF-curvatures were generated numerically via a central difference approximation by using Equation (6).

The damage location index is shown in Figure 2. The indices were calculated for a frequency of 220 rad/s. The estimated location of damage and damage severity index values are shown in Figures 3 to 6. The estimated severity of damage is listed in Table 2. As can be seen, for the damage scenarios analized, the proposed indices are able to indicate the location of the damaged regions of the frame´s beam and the severity of the defects.

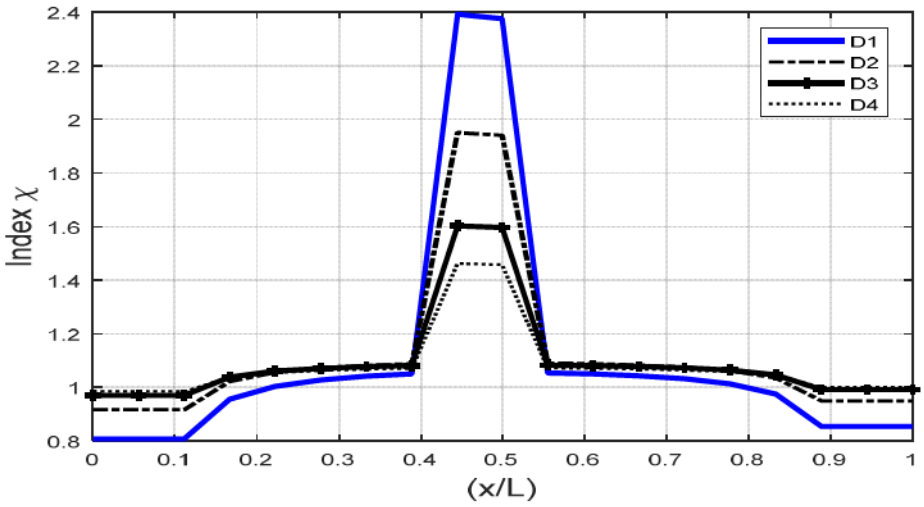

Figure 2. Damage location.

Damage Scenario	Simulated Damage (%)	Estimated Damage (%)	Error (%)
D1	50	52,0	4
D2	40	42,0	5
D3	30	35,0	17
D4	25	30,0	20

Table 2. Damage severity.

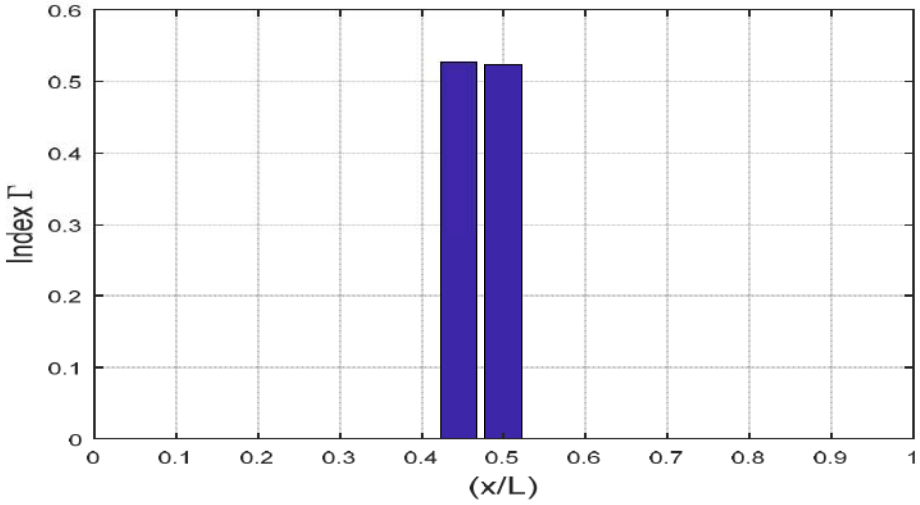

Figure 3. Damage severity index - scenario D1.

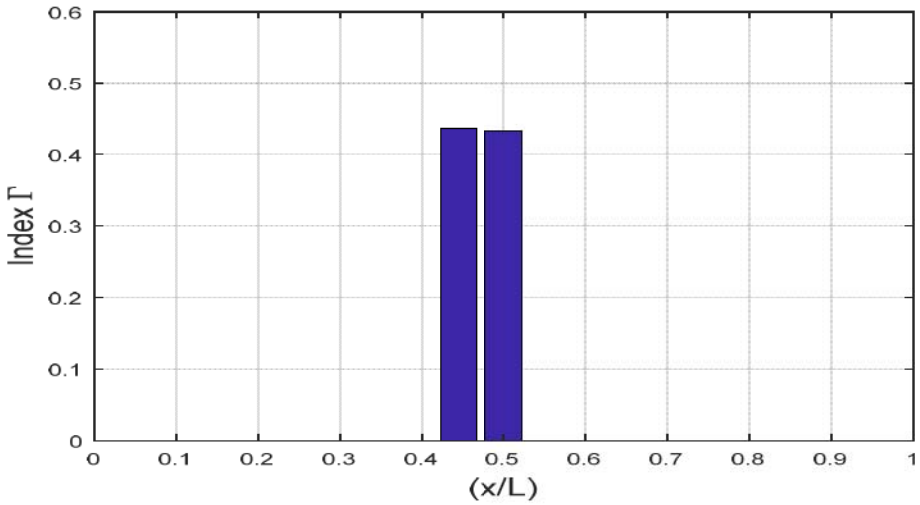

Figure 4. Damage severity index - scenario D2.

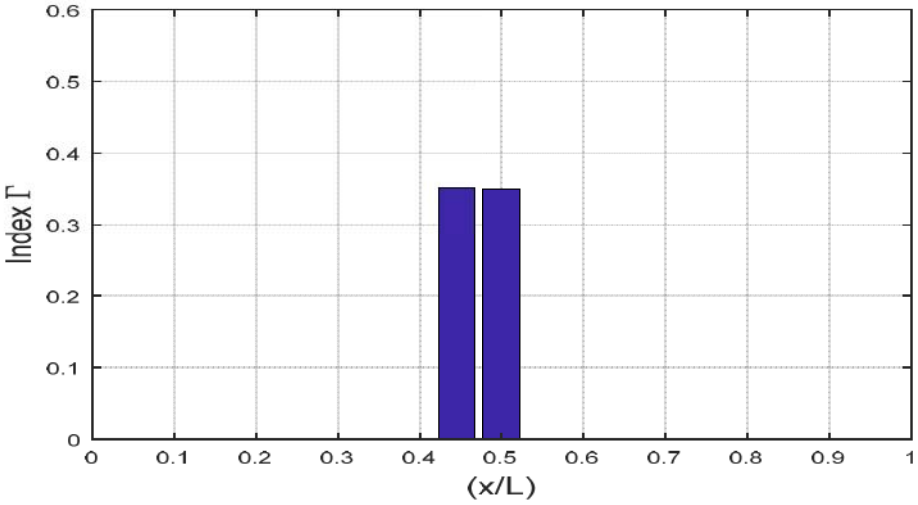

Figure 5. Damage severity index - scenario D3.

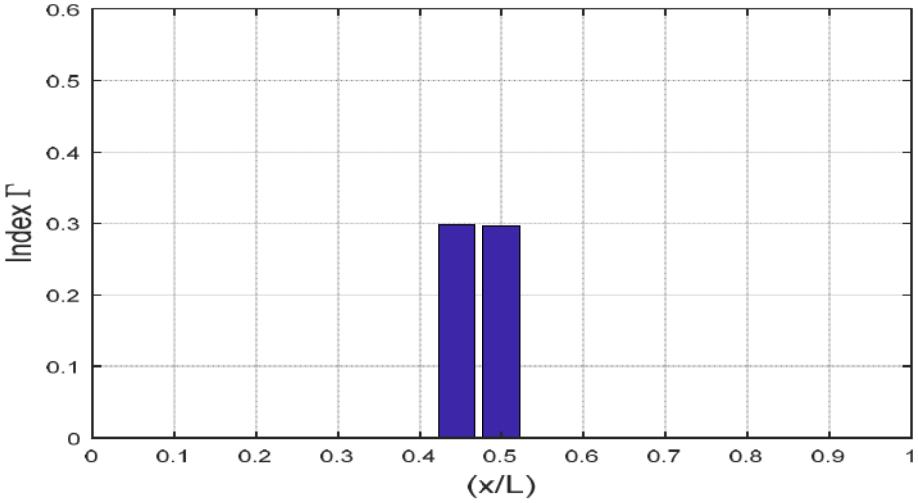

Figure 6. Damage severity index - scenario D4.

5 CONCLUSIONS

This article presents the theoretical formulation of two indices to locate and quantify the severity of the damage in a structure directly from the Frequency Response Function, based on the matrix of FRF-Receptance curvatures. The indices were evaluated for different damage scenarios, varying the severity of the damage in a one-bay frame beam using Timoshenko's beam theory. The results obtained from the numerical simulations indicate that the proposed indexes can locate and estimate the damage severity for single damage scenarios in the analyzed frame. Although errors in the quantification of damage severity were obtained, for practical engineering purposes these could be acceptable. The proposed damage indices could serve as an alternative to the traditional techniques of structural damage identification through modal analysis.

An Axiomatic Formulation for a Class of Multiphysical Systems

Ismael Herrera-Revilla*

*UNAM

ABSTRACT

Axiomatic formulations are very effective for achieving three fundamental paradigms of mathematical and scientific thinking: generality, clarity and simplicity (Herrera and Pinder, 2012). Generality yields an enormous economy of effort in the study and discussion of many subjects; in research, it is invaluable because models possessing it anticipate results for many unforeseen situations. Clarity yields certainty of knowledge. As for simplicity: simplifying ideas permit transforming complicated systems and phenomena into simple ones, which in turn upgrades efficiency and the level of complexity of systems amenable to treatment. For microscopic physical systems Schrödinger equation constitutes a formulation of this kind. Regarding macroscopic systems, it is well known that the groundwork for establishing axiomatic approaches to continuum mechanics was done at the second half of the XX Century by a group of scholars and researchers some of whose most conspicuous leaders were Clifford Truesdell and Walter Noll. The author had the privilege of participating in some of such developments. Based on their results the author has introduced a novel axiomatic formulation that, for macroscopic physical systems, constitutes a counterpart of Schrödinger equation. In this talk, the basic axiomatic formulation of continuous systems is presented and taking it as starting point is extended to a class of multiphysical systems. Then, I present some of the most important applications thus far made. Three-Dimensional Simulations of Failure by Shear Band Formation

Josh Herrington*, Nithin Thomas**, Amine Benzerga***

*Texas A&M; University, **Texas A&M; University, ***Texas A&M; University

ABSTRACT

Analyses of ductile failure by shear banding versus cumulative damage growth by void growth to coalescence are carried out using a coupled plasticity and damage formulation. The constitutive porous metal plasticity relations account for void shape effects, void rotation, plastic anisotropy and void coalescence. The latter is modelled using a separate effective yield function with associated evolution equations of the internal parameters. The resulting model is a hybrid two-surface pressure-sensitive and dilatant plasticity model. The same model is employed to study (i) the effect of plastic anisotropy on crack initiation in round notched bars; (ii) the conditions under which failure occurs subsequent to shear band formation as opposed to void-coalescence induced crack initiation. In particular, an important distinction is made between shear failure and failure in shear. The results obtained show that plastic anisotropy is sufficient to trigger shear band formation in initially round bars.

Site-specific Property Maps of Additively Manufactured Metals Using a Mesoscale, Multi-Physics Modeling Framework

Carl Herriott*, Nadia Kouraytem**, Xuxiao Li***, Wenda Tan****, Vahid Tari*****, Anthony Rollett******, Ashley Spear*******

*University of Utah, **University of Utah, ***University of Utah, ****University of Utah, *****Carnegie Mellon University, ******Carnegie Mellon University, *******University of Utah

ABSTRACT

The microstructure of additively manufactured (AM) metals has been shown to be quite heterogeneous and exotic when compared to conventionally manufactured metals. Consequently, the effective mechanical properties of AM metal parts are expected to vary both within and among different builds due to the laser interaction with the melt pool and solidification characteristics. This work presents a multiphysics modeling framework for simulating the process, microstructure, and properties of AM metal volumes. The framework is entirely automated, from the generation of the microstructure to the resulting spatial-property maps. The framework uses a 3D solidification and nucleation model to simulate a grain-resolved build domain created by a multi-pass, multi-layer, Directed Laser Deposition (DLD) process. The entire build domain is automatically divided into discrete sub-volumes to interrogate site-specific effective mechanical properties. Each sub-volume is first passed into DREAM.3D, where microstructural statistics are recorded, and an input file is written out to simulate mechanical testing on the sub-volume using a parallelized elasto-viscoplastic fast Fourier Transform (EVP-FFT) model. The effective stress-strain response of each sub-volume is analyzed automatically to extract the effective mechanical properties. The Young's modulus is found by applying a Hough transform to the stress-strain response to identify the elastic region. Based on the Young's modulus, a 0.2% yield offset is applied to approximate the yield strength of each sub-volume. Once these effective mechanical properties are found, they are then used to generate heat maps showing how these properties vary spatially throughout the simulated-build domain. As a demonstration, the framework is applied to DLD SS316L volumes with microstructures ranging from fully columnar to fully equiaxed. In this demonstration, we investigate three orthogonal planes (and multiple locations of each plane) throughout each build volume. The first plane, the transverse-direction – build-direction plane, highlights the impact of successive build layers on resulting mechanical properties. The next plane, the transverse-direction - laser-scanning direction plane, highlights variability of the mechanical properties across the build plane at three specific build layers: just above the substrate, mid-build height, and the top of the build volume. Finally, the scanning-direction - build-direction plane, sampled on the center of the track and between two successive tracks, looks at the variability between successive laser tracks. Site-specific property maps are generated for each case to compare the range of properties both within and among each of the build domains. The multiphysics framework and property maps could provide a path toward design and qualification of AM metal parts.

A Multiphase-field Model for Anisotropic Brittle and Ductile Crack Propagation in Cast Iron Brake Discs

Christoph Herrmann*, Felix Schwab**, Ephraim Schoof***, Daniel Schneider****, Britta Nestler*****

*Institute of Digital Materials Science (IDM), Karlsruhe University of Applied Science, Germany, **Institute of Applied Materials - Computational Materials Science (IAM-CMS), Karlsruhe Institute of Technology, Germany, ***Institute of Digital Materials Science (IDM), Karlsruhe University of Applied Science, Germany, ****Institute of Applied Materials - Computational Materials Science (IAM-CMS), Karlsruhe Institute of Technology, Germany, *****Institute of Applied Materials - Computational Materials Science (IAM-CMS), Karlsruhe Institute of Technology, Germany

ABSTRACT

In trucks, brake discs made of cast iron are often used, which, in order to ensure the safety of road users, must satisfy the highest mechanical demands. To calculate the service life of brake discs, it is particularly important to consider crack growth. The material considered in the presentation is cast iron with lamellar graphite and a pearlitic matrix. The perlitic matrix is assumed to be isotropic and ductile, whereas the graphite lamellae are considered to be brittle with an elliptical anisotropy. The phase-field model for crack propagation in multiphase systems by Schneider et al. [1] was extended in order to simulate cracking in the examined material. For the purpose of the model extension, a directional and plasticity dependent crack resistance was introduced. Validation examples of ductile and brittle anisotropic crack propagation are presented. By means of an exemplary cast iron structure, the applicability of the presented model to a multiphase system will be demonstrated. [1] D. Schneider, E. Schoof, Y. Huang, M. Selzer, B., Nestler (2016). Phase-field modeling of crack propagation in multiphase systems. Computer Methods in Applied Mechanics and Engineering, 312, 186-195.

A Micromechanical Damage Model for Brittle Failure of Short Fiber Reinforced Thermoplastics

Patrick Arthur Hessman*, Fabian Welschinger**, Kurt Hornberger***, Thomas Böhlke****

*Karlsruhe Institute of Technology (KIT), Robert Bosch GmbH, **Robert Bosch GmbH, ***Robert Bosch GmbH, ****Karlsruhe Institute of Technology (KIT)

ABSTRACT

Short fiber reinforced thermoplastics (SFRT) have been of great interest to both research and industry due to their high specific stiffness and strength as well as their cost-effective application in semi-structural parts. During the injection-molding process the fibers tend to align with the shear flow in the cavity, resulting in heterogeneous and complex fiber orientation states that significantly influence the mechanical behavior of the finished part. Mean field homogenization models are an attractive class of methods that can be applied to composite materials in order to include the effects of the phase properties, orientation and volume fractions on the effective material behavior and phase stresses and strains. In this work, the Two-Step [1] and Mori-Tanaka [2] homogenization schemes are employed to model the mechanical properties of a dry polyamide 6.6 thermoplastic polymer with a short glass fibers mass fraction of 35% (PA66-GF35). Its microstructural morphology, including the fiber orientation and length distributions, is resolved by means of x-ray micro-computed tomography scans and a single fiber segmentation and analysis procedure. An efficient numerical scheme is applied to include this information in the microstructural model. For the given class of materials and restricting ourselves to monotonic loading, damage and failure is mainly governed by two mechanisms: Initial interfacial debonding and subsequent matrix rupture. The presented approach captures the former by means of a probabilistic interfacial damage model based on the concept of effective inclusions [3] and assuming the interfacial strength to be Weibull-distributed. Matrix rupture is described similarly by an isotropic progressive damage law. Coupled with the mean field schemes, the modeling approach is capable of describing the orientation-dependent progressive failure of the material at hand, which is highlighted by a comparison with experimental data from tensile tests on specimens cut out of injection-molded plates. Numerical Simulation of Debris Flow on General Topography with Pore Pressure Evolution and Hypoplastic Granular Material Behavior

Julian Heß*, Yih-Chin Tai**, Yongqi Wang***

*Technische Universität Darmstadt, **National Cheng Kung University, ***Technische Universität Darmstadt

ABSTRACT

In debris flows, consisting of granular particles and an interstitial fluid, the pore-pressure feedback and the internal contact stress of the grains are mechanisms of importance. These two characteristics play a crucial role and significantly affect the dynamic behaviors: the pore pressure feedback, which reduces the intergranular friction and, hence, enhances the mobility of the whole mixture, and the internal contact stress, which accounts for the non-linear deformational behavior of granular materials. In this work, we present a continuum-mechanical model for debris flows, including two additional internal variables, the extra pore-pressure and the hypoplastic stress, the latter depicting internal friction. These variables are described by a pressure diffusion equation and a transport equation related to the hypoplastic material, respectively. The thermodynamically consistent model is scaled, depth-integrated and embedded in terrain-following coordinates, adapting the concept of general topography in combination with unified coordinates, allowing for the numerically favorable treatment of flows over complex topography. Numerical simulations are performed with this model, applying a shock-capturing non-oscillatory numerical scheme. Parameter studies are performed on the properties of the proposed model, complemented by comparison with experimental data. The results are presented and show that, in comparison to classical debris flow approaches, the proposed model provides a phenomenological insight into the crucial roles and the impact of the pore-pressure feedback and hypoplastic intergranular friction in the flow dynamics.

Acoustic Emissions Damage Detection in Musical Instrument Strings

Mason Hickman*, Prodyot Basu**

*Vanderbilt University, **Vanderbilt University

ABSTRACT

Composite metal strings are used exclusively in amplified instruments such as the electric guitar, which use electromagnetic pickups to transmit the vibration of strings to an output signal. Instrument strings undergo damage from mechanical and environmental wear during their design life. Mechanical wear is caused by low-stress abrasion of the strings on the neck. Over time, the cross section of the strings in the neck region is reduced in area from being repeatedly pressed against the fret wires. When strings are subject to fatigue from continued use, the frequency response characteristics change leading to eventual failure of the string. For this reason, musicians and instrument technicians who make regular use of stringed instruments incur significant costs changing strings on a regular basis. There is a lack of published literature on the behavior of strings with different geometries and material properties subject to this type of tension and fatigue applied over the life of the string. The development of a method to optimize string geometries to obtain a desired frequency response and design life is of great interest to the players of the instrument as well as manufacturers seeking to modernize their production process. As no recognized method currently exists for damage identification and prognosis in instrument strings, the strings are often replaced routinely on an arbitrary basis, irrespective of the actual condition of the strings. The purpose of this research is to develop a tool capable of accurately predicting failure by monitoring and parameterizing transients in the frequency domain. Existing technology can determine the fundamental frequency of the signal for tuning purposes, but neglects the higher-order harmonics in the signal that define the instrument's tonal quality. As the strings are fatigued, the amplitude and frequency of the harmonics present in the signal are shifted and scaled resulting from the damage. This research takes advantage of existing passive sensing and pitch detection technology, but seeks to use the information obtained from sampling the signal more intelligently. The proposed approach uses the available high-frequency information in the signal to characterize damage in the instrument strings. When the instrument is retuned during the life of the strings, the difference between the new signal and the original calibrated signal is measured and used to characterize damage using digital signal processing techniques and empirically trained statistical models. A machine learning approach is used to explore design space and identify combinations of material phases that will optimize the performance of the strings.

Fast Formation and Assembly in Isogeometric Analysis with Applications in Linear Elasticity

Rene Hiemstra*, Francesco Calabro**, Thomas Hughes***, Mattia Tani****, Giancarlo Sangalli*****

*University of Texas at Austin, **Universita degli Studi di Cassino e del Lazio Meridionale, ***University of Texas at Austin, ****Universita di Pavia, Dipartimento di Matematica, *****Universita di Pavia, Dipartimento di Matematica

ABSTRACT

Recently a new formation and assembly strategy was proposed in [1], which resulted in significant speedups in the formation and assembly time of the Galerkin mass matrix in isogeometric analysis. The strategy relies on two key ideas: 1) assembly row by row, instead of element by element; and 2) an efficient formation strategy based on weighted quadrature and sum factorization that is applied to each specific row of the matrix. The resulting computational effort is proportional to the number of degrees of freedom of the trial space. Consequently, this type of formation and assembly scales favorably with polynomial degree, which opens the way for high order isogeometric analysis employing k-refinement. In this work we discuss various important details for the practical implementation of the weighted row-wise formation strategy proposed in [1]. Specifically, we extend the weighted quadrature scheme to accurately integrate the elements of the stiffness matrix in linear elasticity, we propose a new selection of quadrature points that works in the general setting of mixed continuity non-uniform isogeometric spaces and we propose an algorithm for the computation of a corresponding set of quadrature weights. Finally, we show that the row-wise formation strategy allows for the direct construction of the system matrix in the sparse matrix data structure, yielding significant savings in memory operations with respect to standard assembly approaches. Several numerical benchmarks will be shown to illustrate the efficiency and efficacy of the proposed methodology. [1] F. Calabro, G. Sangalli, M. Tani, Fast formation of isogeometric Galerkin matrices by weighted quadrature, Computer Methods in Applied Mechanics and Engineering (2017) 316:606-622.

Discontinuous Galerkin Methods for Layered Ocean Models: Thin Layers and Well-Balanced Forcing

Robert Higdon*

*Oregon State University

ABSTRACT

In a layered ocean model, the vertical coordinate is a quantity related to density, and in a vertical discretization the fluid can be represented as a stack of layers of constant density. Depending on the dynamics of the flow, one or more of these layers can be reduced to near-zero thickness in certain regions. In a DG algorithm, this situation requires a suitable use of limiters and a suitable implementation of horizontal viscosity. In the present work, the viscosity is implemented via the local DG method, as adapted to a barotropic-baroclinic time splitting that is used to address the multiple time scales (external and internal) that are present in ocean dynamics. Another issue in a layered model is the representation of the horizontal pressure forcing. The present work uses a weak Galerkin form of the pressure forcing that is automatically well-balanced in the case of the constant-density, single-layer shallow water equations. In the multi-layer case, this Galerkin form can be implemented using ideas related to the barotropic-baroclinic splitting mentioned above.

ABSTRACT

Recently, the manufacturing technology of various shapes and diameters of carbon fibers has been developed. Therefore, freedom in design of composite microstructure has been improved. In other words, numerous candidates of composite microstructure should be investigated toward the microscopic optimization of composite. To this end, experimental approach, analytical approach, and conventional numerical approach such as finite element method (FEM) are not useful. Experimental approach is costly and time-consuming. Analytical approach cannot be applied to complicated fiber shape such as 2-lobed fiber shape. Conventional FEM is able to handle complicated fiber shape. However, element edge should be aligned with fiber shape and remeshing is inevitable when the microstructure is changed. This limitation makes it difficult to conduct comprehensive numerical investigation. In fact, only a few kinds of fiber shape have been investigated in previous numerical study which utilized the conventional FEM. Consequently, the authors believe that mesh-free microscale simulation tool is required to easily investigate various composite microstructure and to accomplish the microscopic optimization of composite. This study proposes the mesh-free microscale simulation tool which consists of two computational techniques; extended finite element method (XFEM) [1] and the homogenization method using key degree of freedom (DoF) [2]. Firstly, the XFEM with ramp enrichment function [3] was implemented for an efficient simulation of enormous composite microstructures. In this method, the composite microstructure can be modeled independently of the mesh. Secondary, homogenization method was introduced to evaluate an effect of microstructure on the macroscopic material and fracture properties. Here, a key DoF method was incorporated to simply handle the periodic boundary conditions. The validity of the proposed tool was examined by comparing the results against conventional FEM and experiment. Finally, the 3D periodic unit cell simulations of various fiber shapes (circular, elliptical, and 2-lobed) were performed to investigate an effect of fiber shape on the macroscopic material and fracture properties. ABSTRACT

Structural analysis by means of the finite element method (FEM) has become an integral part of the design cycle of shell structures, for buckling, vibration and 3D stress fields analyses. Despite the advances in computational power, these analyses are still being conducted separately with different topologies of structural elements, for instance 2D elements for stability and vibration; and 3D elements for the analyses of detailed stresses. This disparity is largely due to the high computational costs associated with using 3D elements, and inability of 2D elements to capture 3D stress fields, especially in layered structures where through-thickness distortions inform the overall structural behaviour and localised failure initiations. The motive behind our work is to utilise recent advances in computational power and computational mechanics, to derive a hierarchical 2D formulation that can accurately capture both global and local behaviour in shell structures. In doing so, global stiffness and buckling, as well as detailed stress analyses can be performed in a single model. This work presents a new geometrically nonlinear variable kinematics continuum shell (VKCS) formulation based on Carrera's Unified Formulation (CUF), offering capabilities to model shell structures of any geometry with hierarchical axiomatic expansions. The governing equations are derived from the Principle of Virtual Displacements and solved using the finite element method. The shell domain is discretised with charts based on an isoparametric map with no simplifying assumptions made about the geometry. The displacement field is written in a unified formulation, allowing the axiomatic fidelity in the through-thickness direction to be refined in a straightforward and integrated manner. In a linear analysis, the formulation yields excellent, indeed asymptotically correct 3D stresses when compared with 3D-FEM at locations close to the free edges and boundaries, where stresses are inherently three-dimensional in nature. VKCS elements do not require shear correction factors nor 3D stress recovery procedures for accurate stresses. The low computational costs required to achieve converged 3D stress fields with VKCS element makes it an economical alternative to classical 3D-FEM for the analysis of thick and layered shell structures. Finally, we show that numerical results from VKCS in analyses involving geometrical non-linearity are in excellent agreement with benchmarks available in the literature.

Generalized Reproducing Kernel Peridynamics

Michael Hillman*, Guohua Zhou**

*The Pennsylvania State University, **The Pennsylvania State University

ABSTRACT

Peridynamics is a reformulation of the governing equations of solid mechanics into integral equations such that discontinuities are directly admitted in the solution. Typically the implementation is based on satisfaction of the strong form with nodal integration, yielding a meshfree technique. Recently, some initial insights into the relationship between the state-based peridynamic meshfree implementation [1] with the meshfree reproducing kernel particle method [2] have been established for uniform discretizations [3]. This work expands on these efforts by establishing commonality between the two methods in a general, arbitrary setting, and it is shown that the derivative approximations employed in the two methods can be cast into a single framework. Leveraging these new-found relationships, a higher-order peridynamic meshfree method is proposed where optimal convergence can be attained up to arbitrary order, and can also correct deficiencies in the original implementation of state-based peridynamics to ensure linear accuracy. Several numerical examples are given to demonstrate the effectiveness of the proposed formulation. References: [1] S.A. Silling, M.A. Epton, O. Weckner, J. Xu, E. ABSTRACT

In fusion devices, plasma is confined by strong torus-shaped magnetic fields. Two main designs are distinguished, the Tokamak with an axisymmetric field and the Stellarator with a fully 3D field. Physical plasma instabilities, triggered by the interaction between the inhomogeneous mag- netic field and strong density and temperature gradients, can change, deteriorate or even break the confinement [1]. A valid model to study the linear growth and the non-linear interaction of plasma instabilities are the resistive full MHD equations. The numerical simulation of these problems exhibits substantial resolution requirements, demanding for highly accurate schemes and for parallelization and strong scaling of the MHD solver. In addition, with the current Wendel- stein 7-X Stellarator experiments at IPP Greifswald, numerical tools being able to simulate fully three-dimensional, non-axisymmetric configurations are necessary. The MHD simulation starts from a non-trivial steady state of the ideal MHD equations, rep- resenting an equilibrium between gas pressure and magnetic pressure. Then the equilibrium is disturbed and instabilities grow and interact. The equilibrium is computed by specifically de- signed equilibrium solvers, e.g. VMEC [2]. First, we will discuss the generation of three-dimensional high order meshes for Tokamak and Stellarator configurations. The open-source tool HOPR (github.com/fhindenlang/hopr) uses VMEC equilibrium data to generate the mesh, consisting of unstructured and curved hexahedral elements. For the 3D simulations, we employ the highly efficient Discontinuous Galerkin Spectral Element Method [3] implemented in parallel in the open-source FLUXO solver (github.com/project-fluxo) [4], originally developed at IAG in Stuttgart and extended at IPP in Garching and at MI in Cologne. The solver exhibits high parallel efficiency both for weak and strong scaling. We will discuss some details of the implementation and also show benchmark simulations of MHD instabilities. In addition, we discuss recent advances on the formulation and implementation of entropy-stable DGSEM for resistive MHD [5]. [1] J.P. Freidberg, Ideal MHD, Cambridge University Press, 2014 [2] S.P. CFD Simulations for Full-scale Performance Predictions of Ships

Takanori Hino*, Natsumi Murakami**, Tetsuro MIyaji***

*Yokohama National University, **Yokohama National Universityv, ***Yokohama National University

ABSTRACT

Although ship flow CFD methods have reached the stage on which they are routinely used in practical ship hull form design works, most of current applications are for model-scale performance predictions. This is mainly because the conventional ship hull form design is based on the performance of models and CFD simulations are used as alternative to model tests. On the other hand, along with the rapid development of computing power, the demands for full-scale performance predictions by CFD are increasing year by year. The full-scale simulations are expected to give rational propulsive power estimations and wake distributions in ship-scale. However, the full-scale CFD applications are not considered as practical as the model-scale counterparts, since the validation of full-scale computations is not sufficiently accomplished due to the lack of full-scale validation data. The objective of the present paper is to assess the capability of the up-to-date CFD methods for full-scale ship flow simulations. 'Workshop on Ship Scale Hydrodynamic Computer Simulation' organized by Lloyd's Register in 2016 offered the validation data of the full-scale ship. The first test case is taken from this workshop data. The geometries of a ship hull and a propeller and the sea trials records were provided in the workshop. CFD simulations are performed using the up-to-date Navier-Stokes solver. Overset grid capability of the solver is used to cope with the complex geometries of an actual ship. The numerical results are compared with the sea trials data and the level of simulation accuracy is discussed. The second test case is Japan Bulk Carrier (JBC) which was designed for the validation of a ship flow with an energy saving duct and adopted as one of the test cases of CFD Workshop Tokyo 2015. One of the anticipations for full-scale CFD simulations is performance prediction of energy saving devices (ESDs) since the interaction of turbulent wake and ESDs is the most vital factor with a strong scale effect. Although the validation data is available only for model-scale, the full-scale performance predictions are compared with the results of the conventional procedure of extrapolation from model to ship and the scale effect on the ESD performance is assessed. From two test cases above, the present status of full-scale ship flow simulations are reviewed and the future development strategy is discussed.

Construction of the Remote Robot Programming Environment

Shinji Hioki*

*Tezukayama University

ABSTRACT

In order to maintain learner's motivation, we propose the use of "Robots" as efficient educational PSE tools. When we do the robot programming, we need the robots in our laboratory. In this research, we will construct the remote environment in which we can do the robot programming without the robots in our laboratory. By using this environment, anyone who wants to do robot programming can make his research.

Defining Extended CAE Technology toward the Integration of CAE and AI

Tohru Hirano*

*Daikin Information Systems

ABSTRACT

Computer Aided Engineering (CAE) Technology is widely utilized for Innovative Design in the Enterprises in Japan [1]. Recently, Digital Technologies such as IoT and AI are evolving and expanding rapidly to the conventional Industries, and the Design and Development of those products are required drastically changed to adapt to those environment. Here, Extended CAE Technology is defined so as to include not only the Synthesis and Optimization Approach but also the IoT and AI Technology. At first, the history and current range of CAE Technology are reviewed. Then, recent progress of AI Technology is summarized especially on Deep Learning, Reinforcement Learning and Transfer Learning. Concerning to IoT Technology, the key architecture of IoT, that is, Cyber Physical Systems, is described in view of Connected Products and Services as well as Data Assimilation which combines Experiment and Simulation. Finally, Extended CAE Technoloy is proposed for the Design and Development of Connected Products and Services. [1] T. Key words: cohesive fracture, initially rigid, non-differentiable energy minimization, sub-gradient, staggered iteration

Abstract. A dynamic crack propagation algorithm is proposed that relies on the minimization of a non-differentiable potential using a staggered iteration strategy. The solution of each time step entails an iterative two-step scheme, in which the openings are first computed at each interface point through solving a local non-convex optimization problem and then used to update the deformation of the body. Potential crack paths are postulated at inter-element boundaries and cracks are treated as separate entities from the bulk by introducing the crack opening and bulk deformation as independent variables. Using the Nitsche method, the constrained objective potential is written without the need of introducing Lagrange multipliers as additional unknowns. The non-differentiability is treated by exploiting the sub-gradient of the interface potential which allows to relate the interface traction to its opening at the non-differentiability point (i.e. zero opening). Thanks to the non-differentiability, activation happens automatically when a certain level of energy is reached in the body; thus, the method sidesteps the complexities of introducing an extrinsic activation criterion encountered in conventional formulations. Numerical results are presented for the fragmentation of a thick cylinder under impulsive internal pressure in order to show the robustness of the proposed algorithm in modelling complicated dynamic crack propagation problems involving branching and fragmentation.

1 INTRODUCTION

Rigid-cohesive fracture is a versatile tool for fracture analysis in a domain of homogeneous material, in which potential crack paths are not known *a priori* and may include branching and fragmentation. In these models, the transition from the undamaged to the damaged state happens upon satisfaction of an external stress criterion and no displacement jump (opening) occurs prior to activation of the cracks. This is conventionally achieved by adaptively inserting interface elements (or enrichment degrees of freedom in an extended FEM setting) during the course of the simulation whenever and wherever they are needed,[1–5] or, alternatively, through enforcing a zero opening constraint at the interface elements in a Discontinuous Galerkin setting.[6]

It was pointed out[7,8] that in conventional finite element models of rigid-cohesive fracture, the vector of nodal forces is a discontinuous function of the deformation at the time of activation of an interface. As standard finite difference schemes are not developed to deal with discontinuous problems, numerical integration of these models in time presents a number of difficulties. In explicit time stepping computations, it often leads to nonphysical shocks, lack of convergence in the error norm as the time step is refined, over-activation of interfaces and unphysical velocity fields.[7–9] The use of rigid-cohesive models in implicit calculations is also an issue since nonlinear Newton solvers are typically designed for continuous equations and will present difficulties if the equations are discontinuous in their unknowns.

Recently, an energy approach to rigid-cohesive fracture was proposed by Papoulia[10] based on a non-differentiable cohesive potential. The non-differentiability of the cohesive potential is the core of the method and gives the interfaces the property that they do not open until a certain level of stress (or energy) that is encoded in the functional is reached; thus, the method entirely bypasses the activation criterion and its associated difficulties. The approach is distinct from regularized energy formulations such as phase-field[11] and eigenfracture approaches[12] in that it represents cracks as strong discontinuities rather than as smeared cracks. A discontinuous Galerkin implementation of the method was presented by Hirmand and Papoulia.[9] In both works, minimization of the non-differentiable non-convex potential was handled by making use of a continuation strategy along with the trust region minimization algorithm. The present work proposes a new computational algorithm for the minimization of the non-differentiable functional based on a partitioned (staggered) solution strategy and the use of the *sub-gradient*[13] of the interface potential at the non-differentiability point. The method simplifies the implementation of the energy approach of Papoulia[10], making the proposed method well suited for tackling complicated dynamic crack propagation problems involving branching and fragmentation.

2 FORMULATION OF THE ENERGY APPROACH

We follow the formulation of the energy approach proposed by Papoulia[10] and Hirmand and Papoulia.[9] A solid body $\Omega \subset \mathbb{R}^{n_{\mathrm{dim}}}$ $(n_{\mathrm{dim}} = 2, 3)$ is considered, which is bounded externally by $\partial\Omega$ and contains an evolving internal discontinuity boundary $\Gamma_d \subset \mathbb{R}^{n_{\mathrm{dim}}-1}$ representing cracks, as shown in Figure 1. The external boundary $\partial\Omega$, whose unit outward normal is denoted **n**, consists of disjoint parts $\partial_u\Omega$ and $\partial_t\Omega$, on which displacement and traction boundary conditions are

prescribed, respectively. We describe the complete state of deformation of the body by a displacement field $\boldsymbol{u}(\boldsymbol{x},t)\colon \Omega \to \mathbb{R}^{n_{\mathrm{dim}}} \times [0,T)$ and a discontinuity opening field $\boldsymbol{\delta}(\boldsymbol{x},t)\colon \Gamma_d \to \mathbb{R}^{n_{\mathrm{dim}}} \times [0,T)$ and require that

$$[\![\boldsymbol{u}(\boldsymbol{x},t)]\!] - \boldsymbol{\delta}(\boldsymbol{x},t) = \boldsymbol{0} \quad \text{on } \Gamma_d, \tag{1}$$

where $[\![\boldsymbol{u}(\boldsymbol{x},t)]\!]$ is a jump discontinuity of the displacement field on Γ_d. The normal and sliding components of the jump are defined as $[\![u_n]\!] = [\![\boldsymbol{u}]\!] \cdot \boldsymbol{n}_d$ and $[\![\boldsymbol{u}_s]\!] = [\![\boldsymbol{u}]\!] - [\![u_n]\!]\boldsymbol{n}_d$, respectively, where $\boldsymbol{n}_d$ is the unit normal to the discontinuity. Similarly, $\delta_n = \boldsymbol{\delta} \cdot \boldsymbol{n}_d$ and $\boldsymbol{\delta}_s = \boldsymbol{\delta} - \delta_n \boldsymbol{n}_d$. Defining the opening $\boldsymbol{\delta}$ and deformation $\boldsymbol{u}$ as independent variables enables the formulation to treat the crack as an entity separate from the bulk and, therefore, the energy formulation to model the bulk and interface potentials with a certain amount of independence.

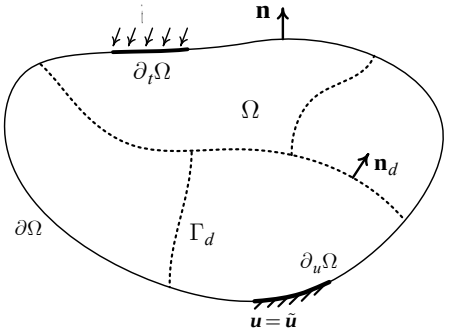

Figure 1. Schematic of a solid body Ω with internal discontinuity boundaries Γ_d.

The potential energy of the elastic body is expressed as the sum of the energy due to the bulk deformation, $\pi_{\mathrm{bulk}}(\boldsymbol{u})$, the energy stored in the interfaces, $\pi_{\mathrm{intf}}(\boldsymbol{\delta})$, the dynamic energy due to inertia, $\pi_{\mathrm{dyn}}(\boldsymbol{u})$, and the energy due to the work of external forces, $W_{\mathrm{ext}}(\boldsymbol{u})$,

$$\pi(\boldsymbol{u},\boldsymbol{\delta}) = \pi_{\mathrm{bulk}}(\boldsymbol{u}) + \pi_{\mathrm{intf}}(\boldsymbol{\delta}) + \pi_{\mathrm{dyn}}(\boldsymbol{u}) - W_{\mathrm{ext}}(\boldsymbol{u}), \tag{2}$$

where

$$\begin{aligned} \pi_{\mathrm{bulk}}(\boldsymbol{u}) &= \int_{\Omega\setminus\Gamma_d} \psi\big(\boldsymbol{\varepsilon}(\boldsymbol{u})\big) dV, \\ \pi_{\mathrm{intf}}(\boldsymbol{\delta}) &= \int_{\Gamma_d} (\phi(\boldsymbol{\delta}) + \theta(\delta_n)) dS, \\ W_{\mathrm{ext}}(\boldsymbol{u}) &= \int_{\Omega\setminus\Gamma_d} \boldsymbol{u}\cdot\boldsymbol{b}\, dV + \int_{\partial_t\Omega} \boldsymbol{u}\cdot\tilde{\boldsymbol{t}}\, dS. \end{aligned} \tag{3}$$

We consider linear elasticity and infinitesimal deformation, for which the strain energy density function ψ in π_{bulk} is

$$\psi\big(\boldsymbol{\varepsilon}(\boldsymbol{u})\big) = \tfrac{1}{2}\boldsymbol{\varepsilon}(\boldsymbol{u})\colon \boldsymbol{D}\colon \boldsymbol{\varepsilon}(\boldsymbol{u}), \tag{4}$$

in which $\boldsymbol{D}$ is the elasticity constitutive tensor and $\boldsymbol{\varepsilon}(\boldsymbol{u}) = \nabla^s \boldsymbol{u} \in \mathbb{R}^{n_{\text{dim}}} \times \mathbb{R}^{n_{\text{dim}}}$ is the symmetric part of the displacement gradient. In the definition of $W_{\text{ext}}(\boldsymbol{u})$, $\boldsymbol{b}$ is the body force per unit volume and $\tilde{\boldsymbol{t}}$ is a prescribed traction vector on $\partial_t \Omega$. The precise form of $\pi_{\text{dyn}}(\boldsymbol{u})$ depends on the particular time stepping scheme employed for temporal discretization.[9,10] In the present work, we have employed the dynamic potential proposed by Hirmand and Papoulia[9] corresponding to the Generalized Newmark scheme. For further details in regards to $\pi_{\text{dyn}}(\boldsymbol{u})$, the reader is referred to the works of Papoulia[10] and Hirmand and Papoulia.[9]

The initially-rigid cohesive energy function ϕ and the interpenetration penalty function θ in π_{intf} are functions of $\boldsymbol{\delta}$ and of $\delta_n = \boldsymbol{\delta} \cdot \boldsymbol{n}_d$, respectively, and are both non-differentiable at their origins ($\boldsymbol{\delta} = \boldsymbol{0}$ and $\delta_n = 0$, respectively). This is the crucial mathematical property that keeps the interfaces closed until a certain level of stress/elastic energy is reached in the body (i.e., initially-rigid behavior), see the discussion by Papoulia.[10] A general class of cohesive models proposed by Ortiz and Pandolfi[1] is considered in which the cohesive potential $\boldsymbol{\phi}(\boldsymbol{\delta})$ is expressed as a function of a scalar effective opening displacement δ, defined as $\delta(\delta_n, \boldsymbol{\delta}_s) = \sqrt{(\delta_n^+)^2 + \beta^2 |\boldsymbol{\delta}_s|^2}$, where $\delta_n^+ = max(\delta_n, 0)$ and β is a material constant that weights the normal and tangential components of the displacement vector. In the present work, the potential employed corresponds to a linear softening behavior similar to the one used by Hirmand and Papoulia.[9] The interpenetration penalty potential $\theta(\delta_n)$ is taken to be the indicator function $I_{\mathbb{R}^+}(\delta_n)$.[9]

The equilibrium of the body is characterized by the solution of the following constrained minimization problem that must be solved at each time step:

$$\text{Find } (\boldsymbol{u}^*, \boldsymbol{\delta}^*) \in \mathcal{U} \times \mathcal{D} \quad \text{minimizing} \quad \pi(\boldsymbol{u}, \boldsymbol{\delta}) \quad \text{subject to} \quad \boldsymbol{g}(\boldsymbol{u}, \boldsymbol{\delta}) = \boldsymbol{0}, \tag{5}$$

where $\mathcal{U}$ and $\mathcal{D}$ are spaces of admissible solutions which depend on the particular finite element implementation and

$$\boldsymbol{g}(\boldsymbol{u}, \boldsymbol{\delta}) = [\![\boldsymbol{u}(\boldsymbol{x}, t)]\!] - \boldsymbol{\delta}(\boldsymbol{x}, t) \tag{6}$$

is a linear constraint function. The Lagrangian for the constrained optimization problem (5) is[9]

$$\mathcal{L}(\boldsymbol{u}, \boldsymbol{\delta}, \boldsymbol{\lambda}) = \pi(\boldsymbol{u}, \boldsymbol{\delta}) + \int_{\Gamma_d} \boldsymbol{\lambda} \cdot \boldsymbol{g} dS, \tag{7}$$

where $\boldsymbol{\lambda}$ is the Lagrange multiplier field. A saddle point of the above Lagrangian corresponds to a solution $(\boldsymbol{u}^*, \boldsymbol{\delta}^*)$ of (5).

3.1 SPATIAL DISCRETIZATION AND THE FINITE DIMENSIONAL PROBLEM

It is noted that taking the derivative of (7) to arrive at a weak form through a variational formulation is not a valid approach in the present setting because the interface potential π_{intf} in (2) is not globally differentiable.[9,10] The finite element discretization is, therefore, directly applied to the

energy functional (7) to arrive at a finite-dimensional, non-differentiable energy minimization problem. In such approach, activation happens automatically when a certain level of energy that is encoded in $\phi(\boldsymbol{\delta})$ is reached.[9,10] The method sidesteps the time-discontinuity and traction lacking issues observed in the literature.[7,8]

We follow Hirmand and Papoulia[9] for the finite element discretization of $\boldsymbol{u}$ and $\boldsymbol{\delta}$. A discontinuous Galerkin discretization is used for the approximation of $\boldsymbol{u}$, whereas a piecewise constant approximation is considered for the approximation of $\boldsymbol{\delta}$. The discontinuous Galerkin discretization $\boldsymbol{u}_h$ is achieved by requiring the neighboring finite elements to not share nodal points and edges, allowing for jump discontinuities $[\![\boldsymbol{u}_h]\!]$ at inter-element boundaries (Figure 2). The union of inter-element boundaries constitutes the discretized discontinuity boundary $\Gamma_{d,h}$ where the cracks can form. The piecewise constant approximation $\boldsymbol{\delta}_h$ is constructed by introducing M nodal points with coordinates $\boldsymbol{\xi}_I \in \Gamma_{d,h}, I = 1, 2, \dots, M$ on the interface (see Figure 2). The location of the nodal points holding opening degrees of freedom is chosen to be the Gauss quadrature points of the interface elements emplaced at the inter-element boundaries of the bulk mesh. As such, each Gauss point of the interface holds an interface opening degree of freedom.

The Lagrange multiplier $\boldsymbol{\lambda}$ is then replaced by a numerical flux due to Nitsche that is only a function of primal variables: $\boldsymbol{\lambda}_h^{DG} = \langle \boldsymbol{\sigma}_h \rangle \boldsymbol{n}_d + \frac{1}{2}\eta \boldsymbol{g}_h$, where $\boldsymbol{\sigma}_h$ is the Cauchy stress tensor computed strongly from $\boldsymbol{u}_h$, η is a sufficiently large penalty number and $\langle * \rangle = \frac{1}{2}(*^+ + *^-)$.

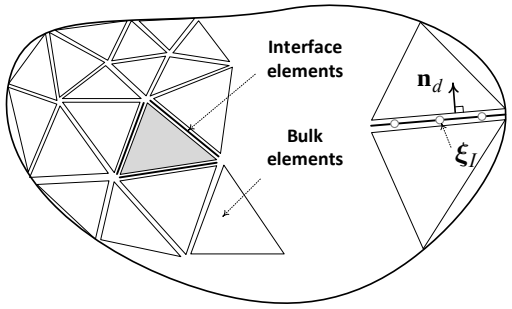

Figure 2. Schematic of the DG discretization Ω_h of the domain and related definitions

Inserting Discontinuous Galerkin approximations $\boldsymbol{u}_h$, $\boldsymbol{\delta}_h$ and the numerical flux $\boldsymbol{\lambda}_h^{\mathrm{DG}}(\boldsymbol{u}_h, \boldsymbol{\delta}_h)$ to the minimization problem (7), the finite-dimensional problem that must be solved at each time step reads:

$$\min_{(\overline{\boldsymbol{u}},\overline{\boldsymbol{\delta}})} \mathcal{L}^{\mathrm{DG}}\left(\overline{\boldsymbol{u}}, \overline{\boldsymbol{\delta}}\right) = \pi(\boldsymbol{u}_h, \boldsymbol{\delta}_h) + \int_{\Gamma_d} \langle \boldsymbol{\sigma}_h \rangle \mathbf{n}_d \cdot \boldsymbol{g}_h dS + \frac{1}{2}\int_{\Gamma_d} \eta \boldsymbol{g}_h \cdot \boldsymbol{g}_h dS\,, \tag{8}$$

where $\overline{\boldsymbol{u}}$ and $\overline{\boldsymbol{\delta}}$ denote the global vector of nodal unknowns corresponding to $\boldsymbol{u}_h$ and $\boldsymbol{\delta}_h$, respectively.

3 STAGGERED MINIMIZATION ALGORITHM

The proposed staggered minimization algorithm relies on the general partitioning approach widely used in the solution of coupled mechanical problems.[14] In such approaches, systems are spatially decomposed into partitions and the solution is advanced in time through solving each partition separately within an iterative solution strategy. Accordingly, we construct a staggered iteration loop in which the minimization problem (7) is solved for $\overline{\boldsymbol{u}}$ and $\overline{\boldsymbol{\delta}}$ independently until convergence is achieved for the coupled problem within the iterations. Minimization with respect to $\overline{\boldsymbol{u}}$ is straightforward since the objective function in (7) is quadratic in and differentiable with respect to $\overline{\boldsymbol{u}}$ everywhere. However, a direct minimization with respect to $\overline{\boldsymbol{\delta}}$ is out of reach due to non-differentiability of ϕ and θ in π_{intf} at their origins with respect to the unknown opening $\overline{\boldsymbol{\delta}}$. We make use of the sub-gradients of ϕ and θ, denoted $\partial\phi$ and $\partial\theta$, respectively, to treat non-differentiability at the non-differentiability points.[13] A brief description of the sub-gradients $\partial\phi$ and $\partial\theta$ is as follows.

As presented by Lorentz,[13] the definition of the sub-gradient of a function coincides with its gradients anywhere it is differentiable. Given that the interface potentials ϕ and θ are differentiable everywhere except at their origins, the points that require special attention are $\boldsymbol{\delta} = \mathbf{0}$ for ϕ and $\delta_n = 0$ for θ. A sub-gradient of ϕ at $\boldsymbol{\delta} = \mathbf{0}$ is given by[13]

$$\partial\phi = \{\boldsymbol{t}_{\text{cohs}} \in \mathbb{R}^{n_{\text{dim}}} \mid t_{\text{cohs}} \leq \sigma_c\}, \tag{9}$$

in which t_{cohs} is an effective norm of $\boldsymbol{t}_{\text{cohs}}$ defined as

$$t_{\text{cohs}} = \sqrt{(t^{+}_{\text{cohs},n})^2 + \beta^{-2}|\boldsymbol{t}_{\text{cohs},s}|^2}, \tag{10}$$

where $t_{\text{cohs},n}$ and $\boldsymbol{t}_{\text{cohs},s}$ are the normal and sliding components of $\boldsymbol{t}_{\text{cohs}}$, respectively, and σ_c is the material strength of the cohesive model. The sub-gradient of θ at $\delta_n = 0$ is given by[13]

$$\partial\theta = \{t_{\text{cont}}\boldsymbol{n}_d \mid t_{\text{cont}} \leq 0,\ \delta_n \geq 0,\ t_{\text{cont}} \cdot \delta_n = 0\}. \tag{11}$$

At all other points, the sub-gradients $\partial\phi$ and $\partial\theta$ coincide with gradients $\nabla_{\boldsymbol{\delta}}\phi$ and $\nabla_{\boldsymbol{\delta}}\theta$, respectively, that is, $\partial\phi = \{\nabla_{\boldsymbol{\delta}}\phi\}$ for $\boldsymbol{\delta} \neq \mathbf{0}$ and $\partial\theta = \{\nabla_{\boldsymbol{\delta}}\theta\}$ for $\delta_n \neq 0$. The two problems to be solved sequentially within the staggered iterations within each time step can be expressed as

$$\min_{\overline{\boldsymbol{u}}} \left\{\pi_{\text{bulk}}(\boldsymbol{u}_h) + \pi_{\text{dyn}}(\boldsymbol{u}_h) - W_{\text{ext}}(\boldsymbol{u}_h) + \int_{\Gamma_d} \boldsymbol{\lambda}_h^{\text{DG}} \cdot \boldsymbol{g}_h dS\right\}, \tag{12-a}$$

$$\min_{\overline{\boldsymbol{\delta}}_I} \left\{\phi(\overline{\boldsymbol{\delta}}_I) + \theta(\bar{\delta}_{n,I}) + \boldsymbol{\lambda}_{h,I}^{\text{DG}} \cdot \boldsymbol{g}_{h,I}\right\} \quad \forall \boldsymbol{\xi}_I \in \Gamma_{d,h}, \tag{12-b}$$

for which the first order minimality conditions are obtained as

$$\boldsymbol{M}\ddot{\overline{\boldsymbol{u}}} + \boldsymbol{K}_{uu}\overline{\boldsymbol{u}} + \boldsymbol{K}_{u\delta}\overline{\boldsymbol{\delta}} - \boldsymbol{F}_{ext} = \mathbf{0}, \tag{13-a}$$

$$\boldsymbol{p}_h - \eta\dot{\overline{\boldsymbol{\delta}}}_I \in \partial\phi(\overline{\boldsymbol{\delta}}_I) \cup \partial\theta(\bar{\delta}_{n,I}) \quad \forall \boldsymbol{\xi}_I \in \Gamma_{d,h}, \tag{13-b}$$

with $\boldsymbol{M}$ (mass matrix), $\boldsymbol{K}_{uu}$ and $\boldsymbol{K}_{u\delta}$ coefficient matrices obtained after taking the gradient of the discretized potential (7), and $\boldsymbol{p}_h = \langle \boldsymbol{\sigma}_h \rangle \cdot \boldsymbol{n}_d + \eta [\![\boldsymbol{u}_h]\!]$.

We note that the particular discretization scheme employed for $\boldsymbol{\delta}_h$ makes the potential of the interfaces separable in each nodal unknown $\overline{\boldsymbol{\delta}}_I$. This leads to independent local minimization problems with respect to $\overline{\boldsymbol{\delta}}_I$ at each Gauss point $\boldsymbol{\xi}_I$ of the interface, see equations (12-b) and (13-b). When the interface potentials are differentiable, solution of the local problem (12-b) is rather straightforward as the gradients of the potentials ϕ and θ are uniquely defined. In this case, equation (13-b) simplifies to $\boldsymbol{p}_h - \eta \overline{\boldsymbol{\delta}}_I = \nabla_{\boldsymbol{\delta}_I} \phi + \nabla_{\boldsymbol{\delta}_I} \theta \quad \forall \boldsymbol{\xi}_I \in \Gamma_{d,h}$ and a minimization algorithm such as the trust region method[15] can be readily used to minimize the objective function (12-b). Note that the choice of a trust-region algorithm is necessary as the objective function in (12-b) is generally not convex in its unknown $\overline{\boldsymbol{\delta}}_I$. Prior to the activation of interfaces, however, or when an activated interface undergoes contact, the minimal solution has to be obtained by exploiting the definition of the sub-gradients equations (9) and (11) at the non-differentiability points. This leads to the following scheme for the treatment of the local minimization problem (12-b) at each interface Gauss point $\boldsymbol{\xi}_I \in \Gamma_{d,h}$:

> IF $\delta_{max} = 0$ and $t_{cohs} \leq \sigma_c$, THEN $\overline{\boldsymbol{\delta}}_I = \boldsymbol{0}$ (pre-activation conditions).
>
> ELSE, solve the minimization problem (12-b) for $\overline{\boldsymbol{\delta}}_I \neq \boldsymbol{0}$. If $p_{h,n} < 0$, set $\bar{\delta}_{n,I} = 0$ and solve for $\overline{\boldsymbol{\delta}}_{s,I}$ only.

In the above, δ_{max} is defined as the maximum effective opening attained up until the current time step; that is, at time t_{i+1}, $\delta_{\max,i+1} = \max_{t' \in \{t_0,\ldots,t_i\}} \delta(t')$.

*Remark 1***.** The staggered minimization algorithm presented here can be used with both explicit and implicit time stepping schemes. For an explicit time stepping scheme, however, the minimization algorithm requires only one staggered iteration to achieve the solution of the next time step. This is because the predictor of the displacement unknowns at the first staggered iteration readily gives the final solution of the time step with no need to correct in subsequent staggered iterations.

*Remark 2***.** In our experience, minimization of the local problem (12-b) normally takes less than ten trust-region iterations to converge when a proper initial estimate is used for the initiation of the trust region minimization algorithm.

4 NUMERICAL SIMULATION RESULTS

We consider the fragmentation of a thick cylinder subjected to impulsive internal pressure in order to demonstrate the robustness of the proposed algorithm in modeling multiple crack growth problems. The problem set-up, material properties and time history of the applied pressure are shown in Figure 3. The internal pressure decays exponentially by time as $p(t) = p_0\, e^{-t/t_0}$, where $p_0 = 400\ MPa$ and $t_0 = 100\ \mu s$. The problem considered here has been previously studied by Song and Belytschko[16] and Hirmand and Papoulia.[9]

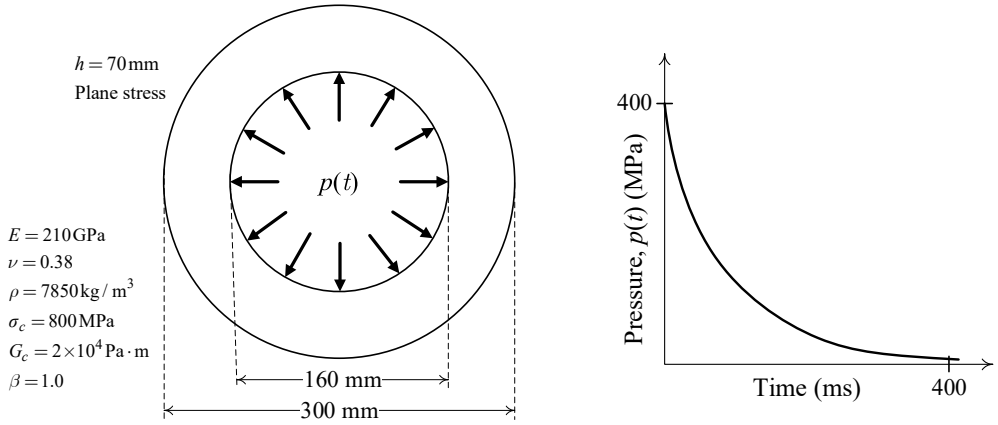

Figure 3. Fragmentation of a thick cylinder; problem definition and relevant properties.

The mesh used consists of 1692 bulk elements, 2394 interface elements and a total of 17334 nodal points (displacement + opening). The dilatational wave speed in the material is $v_d = 5591\ m/s$.[9] An explicit time step would be limited by $\Delta t_{cr} = h_{min}/v_d$, where $h_{min} = 1.2\ mm$ is the minimum element size. We performed the simulations using both explicit and implicit time stepping schemes for a total time of $T = 78\ \mu s$. For the explicit time stepping solution, we used $\Delta t = 0.9\ \Delta t_{cr}$ to ensure stability of the time stepping algorithm. For the implicit time stepping solution, we used $\Delta t = 2\ \Delta t_{cr}$ and considered two different convergence criteria in order to investigate the effect of the number of staggered iterations on the accuracy of the simulation results. In the first case, a sufficiently small tolerance was defined and convergence of the staggered iterations was determined based on the variation of unknown variables $\bar{\boldsymbol{u}}$ and $\bar{\boldsymbol{\delta}}$ in successive iterations. Staggered iterations were allowed to continue until convergence to this pre-determined tolerance was achieved. In the second case, the number of staggered iterations was limited to a maximum of 3 iterations, irrespective of the magnitude of the terminal errors. The final deformed configurations and the activation patterns obtained in different simulations are shown in Figures 4 and 5, respectively. Results obtained by different schemes show good agreement. In addition, results are comparable to those reported in the literature by Hirmand and Papoulia[9] and Song and Belytschko.[16]

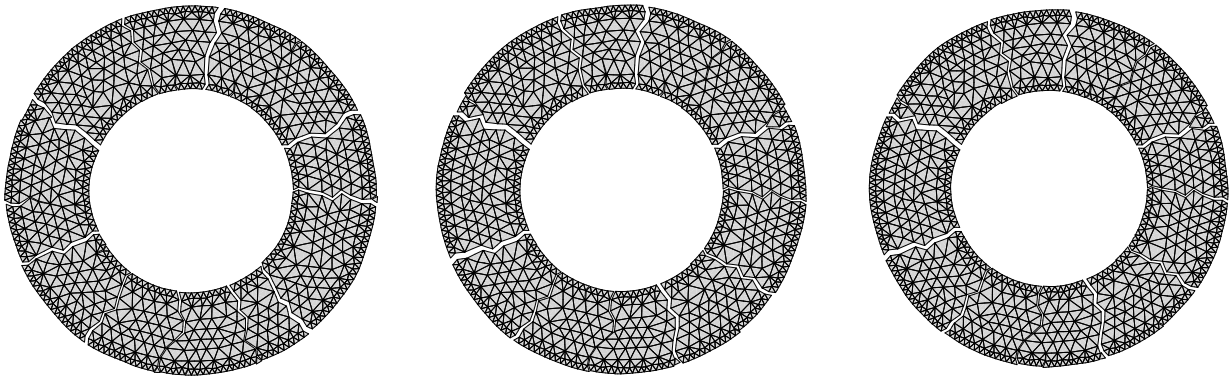

Figure 4. Fragmentation of a thick cylinder; final deformed meshes (magnified 10 times) obtained by (a) explicit time stepping (b) implicit time stepping until convergence and (c) implicit time stepping, three iterations

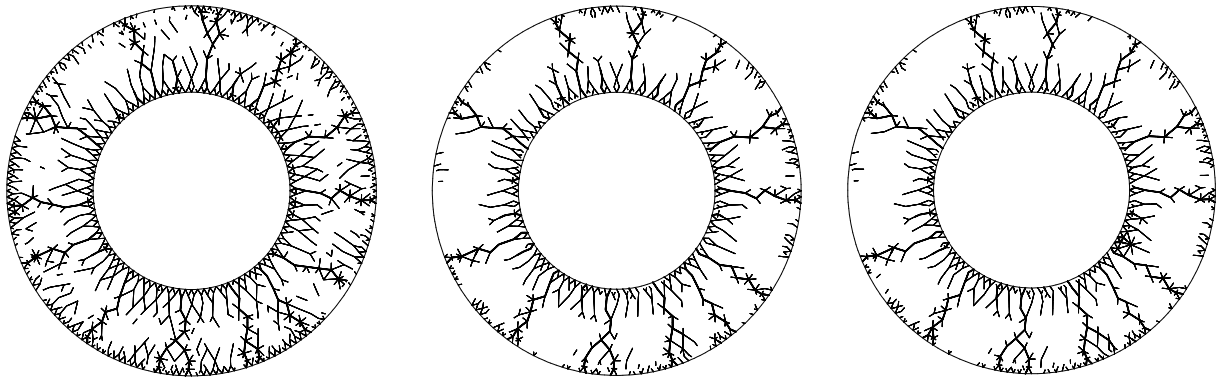

Figure 5. Fragmentation of a thick cylinder; interface activation patterns obtained by (a) explicit time stepping (b) implicit time stepping until convergence and (c) implicit time stepping, three iterations.

Finally, the convergence profile of the converged staggered iterations is shown in Figure 6 at three representative time steps corresponding to post failure of the interfaces (prior to failure of the interfaces, the staggering scheme converge in one iteration since the equations are linear). The convergence profiles show stable behavior indicative of the robustness of the proposed staggered solution strategy.

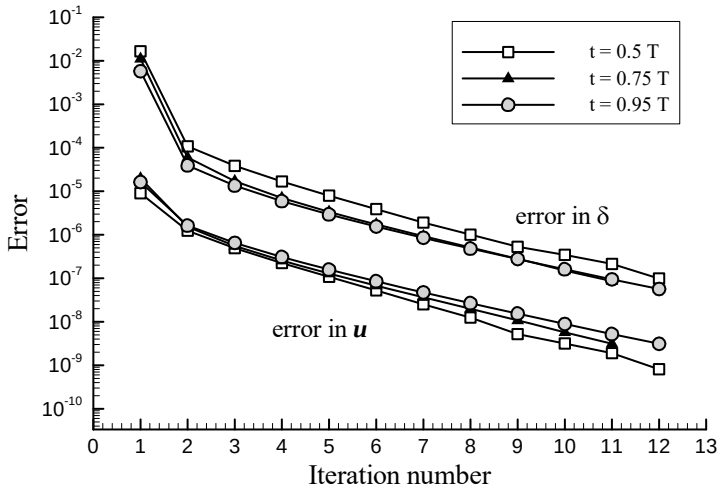

Figure 6. Convergence profile of the staggered iterations in implicit calculations.

5 CONCLUSION

A new computational algorithm was presented for rigid-cohesive fracture on the basis of non-differentiable energy minimization. The method entails a staggered solution strategy in which minimization is performed with respect to the bulk deformation and with respect to crack opening unknowns independently. The method offers several advantages over a monolithic approach as the differentiable, convex part and the non-differentiable, non-convex part of the problem are solved separately. The use of the sub-gradient concept for treatment of the non-differentiability, together

with the particular discretization scheme employed for the interface openings, simplifies minimization of the non-differentiable, non-convex part of the potential significantly. In addition, the partitioned solution strategy offers desirable flexibility from a computer programming perspective: the method can be implemented within an existing solid mechanics finite element code with minimal effort.

Numerical Analysis of Crack Propagation in Tempered Glass Plate

ABSTRACT

The fracture of the thermally tempered glass results in the complex crack patterns with a large number of small fragments. The prediction of the shape of the fragments in fractured tempered glass is required for the product safety, because sharp edge brings harmful risk to users. However, no effective numerical method for the estimate of crack paths in tempered glass has been proposed so far. This research presents the numerical analysis method to simulate the dynamic fracture process in thermally tempered glass plate. The tempered glass has the spatial distribution of the residual stress in both in-plane and cross-section direction resulting from the thermal tempering process. The crack paths and the shape of the fragments change depending on the residual stress distribution. This implies that the residual stress pattern plays a significant role for the fracture behavior in the tempered glass. Particle Discretization Scheme Finite Element Method (PDS-FEM) is one of the fracture analysis methods for the solid continuum. PDS-FEM applies the particle discretization to the field variables by using discontinuous and non-overlapping shape functions defined on the conjugate geometries: Delaunay tessellation and Voronoi tessellations. We implement the treatment of the residual stress field to PDS-FEM. In the framework PDS-FEM, the solid continuum is expressed by the set of the Voroni particles. According to the particle discretization, PDS-FEM can define the Hamiltonian of the system to provide the time evolution of the dynamic behavior of the linearly elastic body. Also, this discretization scheme can evaluate the displacement field expressed by the translational motion of the rigid body particles with the same accuracy as the ordinary FEM. These advantages of PDS-FEM enable us to evaluate the release and the re-distribution of the residual stress in the process of the dynamic crack propagation. We could demonstrate that the crack patterns and the crack propagation process obtained from the preliminary numerical analysis are analogous to those typically observed in the fracture of the thermally tempered glass. This ensures that the proposed numerical analysis method successfully captures the fundamental mechanism for the dynamic crack propagation in the thermally tempered glass.

Finite Element Modeling and Simulation of Failure in Heterogeneous Composite-Metal Layers

Franz Hirsch*, Markus Kästner**

ABSTRACT

Modern lightweight structures, e.g. in automotive and aircraft applications, exploit their full potential utilizing a multi-material design. Hence, it is convenient to apply isotropic lightweight metals in regions with a complex three-dimensional stress state and fiber-reinforced polymers (FRP) in regions with determined loading directions. These design approaches require suitable joining strategies. Next to common joining technologies based on bolts and rivets or bonding agents, intrinsic interlocking joints are a promising solution [1]. On the microscale, such connections can be achieved with defined surface structures of the metal component, so that the polymer matrix fills the gaps and form a contour joint. The comprehension of the damage process is valuable during the design process and often hard to determine experimentally, where numerical investigations are suitable means. In this contribution, a finite element model of a representative boundary layer [2] between a metal component and an FRP is presented, to study the complex failure behavior and damage mechanisms under mechanical loading. We distinguish adhesive failure of the metal-polymer and the fiber-polymer interface and cohesive failure of the polymer material. The behavior of the polymer is described by an elastic-plastic damage model at large strains with a regularization to avoid the typical mesh dependence of softening material models. Local adhesive failure is modeled by a cohesive zone approach based on a traction-separation formulation. The application of a homogenization scheme for adhesive layers [3] enables the extraction of effective traction-separations relations and the determination characteristic interface properties. The numerical studies show, that rough or structured metal-polymer interfaces shift the dominant damage mechanism from pure adhesive to cohesive failure of the polymer and therefore to an increased effective strength of the boundary layer. This effect occurs especially under shear loading, which correspond to the typical observations of higher shear strengths compared to the values in tension direction. References [1] R. Kießling, J. ABSTRACT

Structural optimization requires a suitable mix of an accurate geometric description and an efficient analysis model. Isogeometric Analysis (IGA) fills this need, as it reconciles computer-aided design (CAD) with structural analysis by using spline functions as finite element bases. Since CAD uses the boundary representation (B-rep), IGA is especially suitable for analyzing structures whose geometry is easily derived from a surface, as is the case for shells. Therefore, the efficiency of IGA-based shape optimization of shells has been observed [1-2] and capable algorithms have been proposed. However, its applicability to complex structures as skin stiffened aerostructures is not yet proven. Non-conforming interface [3] between the stiffeners and the skin is needed in order to get an attractive design space. The simplicity and the efficiency of the coupling depends on the chosen shell formulation. We explore and compare the use of two formulations: the Kirchhoff-Love formulation for thin shells and a solid-shell model for thicker shells. Starting from numerical examples involving simple stiffened panels, the final goal is to propose a general framework for optimizing the buckling behavior of large and complex aeronautical structures. ABSTRACT

Decades ago, when memory was a scarce resource, computational scientists routinely worked in single precision and were more sophisticated in dealing with the pitfalls finite-precision arithmetic. Today, however, we typically compute and store results in 64-bit double precision by default even when very few significant digits are required. Many of these bits are representing errors – truncation, iteration, roundoff – instead of useful information about the solution. This over-allocation of resources is wasteful of power, bandwidth, storage, and FLOPs; we communicate and compute on many meaningless bits and do not take full advantage of the computer hardware we purchase. Because of the growing disparity of FLOPs to memory bandwidth in modern computer systems and the rise of General-Purpose GPU computing – which has better peak performance in single precision – there has been renewed interest in mixed precision computing, where tasks are identified that can be accomplished in single precision in conjunction with double precision. Such static optimizations reduce data movement and FLOPs, but why stop there? We often adapt mesh size, order, and models when simulating to focus the greatest effort only where needed. Why not do the same with precision? At LLNL, we are developing the methods and tools that will enable the routine use of dynamically adjustable precision at a per-bit level depending on the needs of the task at hand. Just as adaptive mesh resolution frameworks adapt spatial grid resolution to the needs of the underlying solution, our goal is to provide more or less precision as needed locally. We will discuss a new technique based on local, adaptive floating-point compression to address the data bandwidth problem within simulations and repurpose a defect correction technique that can adaptively reduce the cost of floating point operations. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

A Development of Polygonal Finite Shell Element and Its Application to Coupling Non-matching Meshes

Thuan Ho Nguyen Tan*, Hyun-Gyu Kim**

*Seoul National University of Science and Technology, **Seoul National University of Science and Technology

ABSTRACT

In this work, a polygonal shell formulation on arbitrary polygonal meshes is developed for shell analysis. Assumed natural strains in the form of the mixed interpolation of tensorial components (MITC) approach are employed to avoid the transverse shear locking when the thickness of shell tends to zeros. In addition, an assumed membrane strain field is constructed to alleviate the membrane locking by a linear combination of the tying membrane strains. The non-matching meshes can be effectively connected by the polygonal shell elements at non-matching interfaces. Several basic tests and practical examples are performed to verify the present method. Domain Decomposition Least-squares Petrov--Galerkin (DD-LSPG) for Nonlinear Model Reduction

Chi Hoang*, Kevin Carlberg**

*Sandia National Laboratories, **Sandia National Laboratories

ABSTRACT

Many tasks in computational science and engineering are \textit{many query} in nature: they require the repeated simulation of a parameterized computational model. Model reduction has become a popular approach to make such tasks tractable. Such techniques first perform an `offline' training stage during which the computational model is simulated for multiple parameter instances. Then, during an `online' deployed stage, these techniques reduce the dimensionality and complexity of the original computational model at arbitrary parameter instances by performing a projection process onto a low-dimensional subspace. While such reduced-order models (ROMs) have demonstrated success in many applications, challenges arise when applying model reduction either to \textit{extreme-scale models} or to \textit{decomposable systems}, i.e., systems composed of well-defined components. In the former case, the extreme-scale nature of the original computational model renders the offline training simulations infeasible. In the latter case, the many-query task often involves design, wherein components are swapped or their interconnecting topology is modified; in this case, the original computational model changes between queries, rendering training simulations (which assume a fixed original computational model) challenging. To address these problems, we propose a domain-decomposition least-squares Petrov--Galerkin (DD-LSPG) model-reduction method. Rather than constructing a low-dimensional subspace for \textit{the entire state space}, low-dimensional subspaces are constructed for different subdomains or components characterizing the original model. During the offline stage, only \textit{subdomain training simulations} are needed in the case of extreme-scale models, and only \textit{component training simulations} are required in the case of decomposable systems. During the online stage, the approach constructs a LSPG model for each subdomain/component (including hyper-reduction in the case of nonlinearities), and enforces (weak) compatability on the `ports' connecting them. Mathematically, the resulting ROM corresponds to a nonlinear least-squares problem with linear equality constraints. We propose several different strategies for defining the ingredients characterizing the methodology: (i) three different ways to construct basis functions on the interface/ports of subdomains (which imply different offline training strategies), (ii) different methods for enforcing compatibility (iii) four different solvers that expose different levels of concurrency and intrusiveness. Numerical results performed on problems in heat transfer and fluid dynamics demonstrate that the proposed method outperforms typical model-reduction techniques in terms of both accuracy and (parallel) computational time.

Key words: Wave Finite Element, Railway Dynamics, Periodic Structure, Waveguide, Computing Methods.

Abstract. Based on the finite element method, the wave finite element method (WFE) permits to analyze the dynamics of a periodic structure by using a wave decomposition on one period. This method reduces the number of DOF and it has advantages in calculation time. However, it cannot be applied easily to a railway track because this structure is subjected to moving loads which are not considered in a classical WFE. In this article, we present a technique to deal with moving loads applying in a railway track where the track components are modeled by 3D continuous media. By using the classical WFE for one track period in frequency domain, we can rewrite the vector of DOF and loads in a wave base. Then, we can calculate the wave amplitudes of the moving loads from their representation in this base. Thereafter, we apply the wave analyze of WFE to the hold structure. The result shows that the moving loads lead to a sum of wave amplitudes. Finally, we apply this method for a railway track subjected to constant moving loads with numerical application. The new technique permits to analyze the dynamic of railway tracks by considering only one track period.

1 INTRODUCTION

The dynamic of railway track has been studied with different methods. The analytical methods permit to calculate very fast track responses for different types of tracks [1-6]. These methods base on the model of beams supported by a viscoelastic foundation or the model of periodically supported beams [6]. The numerical methods have been developed by using the finite element method (FEM). The advantage of this method is to give a complete analysis. However, it can not take easily the whole length of the railway track and the calculation time is long. Some reduced techniques have been developed for the FEM. Recently, the wave finite element method [7-10] has been applied to the railway track analysis. This method is based on the wave decomposition of one track period then

using the wave analysis to compute the response of the whole track. However, the classical WFE can not take into account the moving loads of a train applied to the rail and this article deals with this problem.

By rewriting the dynamic equation of one period (a substructure) of the railway track subjected to a load in the frequency domain, we obtain a relation for the vector of DOF and nodal loads at the left and right boundary of the substructure and this relation is including the moving loads. Then, we use the WFE technique to rewrite the expression of the track response. On the other side, we present a bounded limit for an infinite periodic railway track which leads to a simple expression of the response. The applications have been developed then for a normal railway track and ones with a defect zone or a transition zone.

1.1 Dynamic equation

Consider a railway track with a periodic interval as shown in Figure 1. This interval is represented by one period (a substructure) with all components of the tracks (rails, pads, supports, fondations...). The track is subjected to dynamic loads of a train and we consider that all loads are given.

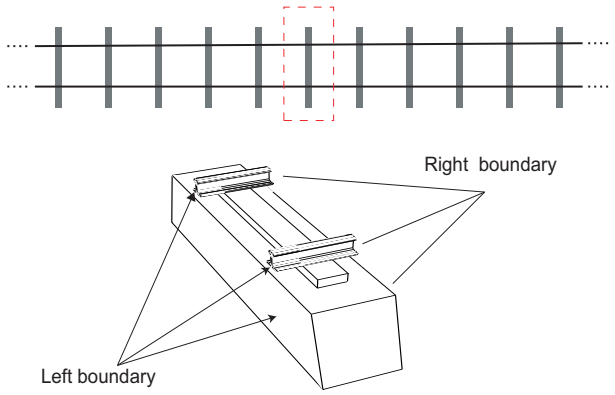

Figure 1: Periodic railway track represented by a substructure

By using the finite element method for a substructure, the dynamic equation can be written as follows

$$\mathbf{D}_{tot}\mathbf{q} = \mathbf{F} \tag{1}$$

where $\mathbf{D}_{tot} = \mathbf{K} + j\omega\mathbf{C} - \omega^2\mathbf{M}$ is the dynamic stiffness matrix (DSM) of the substructure. We note that the aforementioned equation holds for all type of modeling (beam, 2D or 3D). Then, we can rewrite the DSM as follows

$$\begin{bmatrix} \tilde{\mathbf{D}}_{II} & \tilde{\mathbf{D}}_{IL} & \tilde{\mathbf{D}}_{IR} \\ \tilde{\mathbf{D}}_{LI} & \tilde{\mathbf{D}}_{LL} & \tilde{\mathbf{D}}_{LR} \\ \tilde{\mathbf{D}}_{RI} & \tilde{\mathbf{D}}_{RL} & \tilde{\mathbf{D}}_{RR} \end{bmatrix} \begin{bmatrix} \mathbf{q}_I \\ \mathbf{q}_L \\ \mathbf{q}_R \end{bmatrix} = \begin{bmatrix} \mathbf{F}_I \\ \mathbf{F}_L \\ \mathbf{F}_R \end{bmatrix} \tag{2}$$

where L, R and I denote for the left, right boundaries and inner nodes of the substructure as shown in Figure 1. Then, we can reduce the inner nodes $\mathbf{q}_I$ of the cell from the first

row of equation (2) and we obtain

$$\begin{bmatrix} \mathbf{D}_{LI}\mathbf{F}_I \\ \mathbf{D}_{RI}\mathbf{F}_I \end{bmatrix} + \begin{bmatrix} \mathbf{D}_{LL} & \mathbf{D}_{LR} \\ \mathbf{D}_{RL} & \mathbf{D}_{RR} \end{bmatrix} \begin{bmatrix} \mathbf{q}_L \\ \mathbf{q}_R \end{bmatrix} = \begin{bmatrix} \mathbf{F}_L \\ \mathbf{F}_R \end{bmatrix} \tag{3}$$

where

$$\begin{array}{ll} \mathbf{D}_{LL} = \tilde{\mathbf{D}}_{LL} - \tilde{\mathbf{D}}_{LI}\tilde{\mathbf{D}}_{II}^{-1}\tilde{\mathbf{D}}_{IL} & \mathbf{D}_{LR} = \tilde{\mathbf{D}}_{LR} - \tilde{\mathbf{D}}_{LI}\tilde{\mathbf{D}}_{II}^{-1}\tilde{\mathbf{D}}_{IR} \\ \mathbf{D}_{RL} = \tilde{\mathbf{D}}_{RL} - \tilde{\mathbf{D}}_{RI}\tilde{\mathbf{D}}_{II}^{-1}\tilde{\mathbf{D}}_{IL} & \mathbf{D}_{RR} = \tilde{\mathbf{D}}_{RR} - \tilde{\mathbf{D}}_{RI}\tilde{\mathbf{D}}_{II}^{-1}\tilde{\mathbf{D}}_{IR} \\ \mathbf{D}_{LI} = \tilde{\mathbf{D}}_{LI}\tilde{\mathbf{D}}_{II}^{-1} & \mathbf{D}_{RI} = \tilde{\mathbf{D}}_{RI}\tilde{\mathbf{D}}_{II}^{-1} \end{array} \tag{4}$$

We see that equation (3) presents a relation between the loads and displacements at the left and right boundaries of a cell. This equation contains a term of $\mathbf{F}_I$ which is zero when the substructure has non external loads.

1.2 Boundary conditions

We denote (n) for the substructure number n in the track interval. For the two consecutive substructures, the right boundary of (n) is the left boundary of $(n+1)$. Therefore, we have

$$\begin{array}{l} \mathbf{q}_R^{(n)} = \mathbf{q}_L^{(n+1)} \\ \mathbf{F}_R^{(n)} + \mathbf{F}_L^{(n+1)} = \mathbf{F}_{\partial R}^{(n)} \end{array} \tag{5}$$

where $\mathbf{F}_{\partial R}^{(n)}$ is the external load at the right boundary R of the substructure (n). By combining equations (3) and (5), we obtain

$$\begin{bmatrix} \mathbf{q}_L^{(n+1)} \\ -\mathbf{F}_L^{(n+1)} \end{bmatrix} = \begin{bmatrix} \mathbf{D}_{qI}\mathbf{F}_I^{(n)} \\ \mathbf{D}_{fI}\mathbf{F}_I^{(n)} - \mathbf{F}_{\partial R}^{(n)} \end{bmatrix} + \mathbf{S} \begin{bmatrix} \mathbf{q}_L^{(n)} \\ -\mathbf{F}_L^{(n)} \end{bmatrix} \tag{6}$$

where

$$\mathbf{S} = \begin{bmatrix} -\mathbf{D}_{LR}^{-1}\mathbf{D}_{LL} & -\mathbf{D}_{LR}^{-1} \\ \mathbf{D}_{RL} - \mathbf{D}_{RR}\mathbf{D}_{LR}^{-1}\mathbf{D}_{LL} & -\mathbf{D}_{RR}\mathbf{D}_{LR}^{-1} \end{bmatrix}, \tag{7}$$

and

$$\begin{bmatrix} \mathbf{D}_{qI} \\ \mathbf{D}_{fI} \end{bmatrix} = \begin{bmatrix} -\mathbf{D}_{LR}^{-1}\mathbf{D}_{LI} \\ \mathbf{D}_{RI} - \mathbf{D}_{RR}\mathbf{D}_{LR}^{-1}\mathbf{D}_{LI} \end{bmatrix} \tag{8}$$

We can rewrite equation (6) as follows

$$\mathbf{u}^{(n+1)} = \mathbf{S}\mathbf{u}^{(n)} + \mathbf{b}^{(n)} \tag{9}$$

where

$$\mathbf{u}^{(n)} = \begin{bmatrix} \mathbf{q}_L^{(n)} \\ -\mathbf{F}_L^{(n)} \end{bmatrix}, \quad \mathbf{b}^{(n)} = \begin{bmatrix} \mathbf{D}_{qI}\mathbf{F}_I^{(n)} \\ \mathbf{D}_{fI}\mathbf{F}_I^{(n)} - \mathbf{F}_{\partial R}^{(n)} \end{bmatrix} \tag{10}$$

Equation (9) presents a relation between DOF (displacements and loads) of a substructure (n) and its next substructures $(n+1)$. Here $\mathbf{b}^{(n)}$ presents the external loads on the substructure (n) (hence, when the substructure is free, $\mathbf{b}^{(n)} = 0$). For a series

of substructures, this equation presents a geometric series which can be reduced to the following results

$$\mathbf{u}^{(n)} = \mathbf{S}^n \mathbf{u}^{(0)} + \sum_{k=1}^{n} \mathbf{S}^{n-k} \mathbf{b}^{(k-1)} \tag{11}$$

$$\mathbf{u}^{(0)} = \mathbf{S}^n \mathbf{u}^{(-n)} + \sum_{k=0}^{n-1} \mathbf{S}^{k} \mathbf{b}^{(-k)} \tag{12}$$

Equations (11) and (12) give the relations of the responses at the substructure (n) and $(-n)$ respectively, and the response at the reference origin. Note that the origin can be placed at any substructure because the railway track is periodic.

1.3 Load of a train

The load of a train applying on one period (n) of the track is presented by a dynamic force $f_n(x,t)$ with x is local position and t is the time. In the frequency domain, when using the finite element method, the nodal load on the rail at the period n in the moving reference is presented by $\mathbf{f}_n(\omega)$. In the fixed reference, the load on the period (n) is presented by $f_n\left(x, t + \frac{nl}{v}\right)$ with l is the length of one period and v is the train speed. Thus, the nodal load in the frequency domain is given by

$$\mathbf{F}_*^{(n)}(\omega) = \mathrm{e}^{\mathrm{i}\omega\frac{nl}{v}} \mathbf{f}_*^{(n)}(\omega) \tag{13}$$

where $\mathbf{F}_*$ can be $\mathbf{F}_I$ or $\mathbf{F}_{\partial R}$. We see that when the train load is stable, $\mathbf{f}_*^{(n)}(\omega)$ does not depend on n and the load on all period has the same spectrum but different phases given by the first term $\mathrm{e}^{\mathrm{i}\omega\frac{nl}{v}}$.

Bounded conditions: We suppose that the train move on an limited interval of the track and therefore, the track response at infinity are bounded

$$\lim_{n\to\pm\infty} \{\mathbf{q}^{(n)}, \mathbf{F}^{(n)}\} \text{ are bounded} \tag{14}$$

2 WAVE DECOMPOSITION

2.1 Calculation of wave base

We will now calculate the eigenvalues and eigenvectors $\{\mu_j, \phi_j\}_j$ of the matrix $\mathbf{S}$ given by equation (9). By definition, we have

$$\mathbf{S}\phi_j = \mu_j \phi_j \tag{15}$$

Due to the symplectic nature of the matrix $\mathbf{S}$, we consider the eigenproblem of the transformation $\mathbf{S} + \mathbf{S}^{-1}$ which yields eigenvalues of the form $\lambda_j = \mu_j + 1/\mu_j$ given by [9]

$$\left[\left(\mathbf{N}'\mathbf{J}\mathbf{L}'^T + \mathbf{L}'\mathbf{J}\mathbf{N}'^T\right) - \lambda_j \mathbf{L}'\mathbf{J}\mathbf{L}'^T\right] \mathbf{z}_j = 0 \tag{16}$$

where

$$\mathbf{L}' = \begin{bmatrix} \mathbf{0} & \mathbf{I}_n \\ \mathbf{D}_{LR} & \mathbf{0} \end{bmatrix}, \quad \mathbf{N}' = \begin{bmatrix} \mathbf{D}_{RL} & \mathbf{0} \\ -(\mathbf{D}_{LL} + \mathbf{D}_{RR}) & -\mathbf{I}_n \end{bmatrix}, \quad \mathbf{J} = \begin{bmatrix} \mathbf{0} & \mathbf{I}_n \\ -\mathbf{I}_n & \mathbf{0} \end{bmatrix} \tag{17}$$

Thereafter, each pair of eigenvalues $(\mu_j, \mu_j^\star)$ can be computed analytically by the quadratic equation $(x^2 - \lambda_j x + 1 = 0)$. Also, the eigenvectors corresponding to these eigenvalues are computed by the closed-form expressions

$$\phi_j = \begin{bmatrix} \mathbf{I}_n & \mathbf{0} \\ \mathbf{D}_{RR} & \mathbf{I}_n \end{bmatrix} \mathbf{w'}_j, \quad \phi_j^\star = \begin{bmatrix} \mathbf{I}_n & \mathbf{0} \\ \mathbf{D}_{RR} & \mathbf{I}_n \end{bmatrix} \mathbf{w'}_j^\star \tag{18}$$

where $\mathbf{w'}_j = \mathbf{J}(\mathbf{L'}^T - \mu_j^\star \mathbf{N'}^T)\mathbf{z}_j$ and $\mathbf{w'}_j^\star = \mathbf{J}(\mathbf{L'}^T - \mu_j \mathbf{N'}^T)\mathbf{z}_j$.

If we note $\mathbf{\Phi} = [\phi_1 \cdots \phi_n]$ and $\mathbf{\Phi}^\star = [\phi_1^\star \cdots \phi_n^\star]$, we have a wave base $\{\mathbf{\Phi}, \mathbf{\Phi}^\star\}$ of the transformation $\mathbf{S}$. We can also separate the components of the wave base corresponding to $\mathbf{q}, \mathbf{F}$ as follows

$$\mathbf{\Phi} = \begin{bmatrix} \mathbf{\Phi}_q \\ \mathbf{\Phi}_F \end{bmatrix} \quad \mathbf{\Phi}^\star = \begin{bmatrix} \mathbf{\Phi}_q^\star \\ \mathbf{\Phi}_F^\star \end{bmatrix} \tag{19}$$

Orthogonality and normalisation: the wave base is symplectic orthogonal in the meaning of $\phi_j^T \mathbf{J} \phi_i = \phi_j^{\star T} \mathbf{J} \phi_i^\star = 0$ $(\forall i, j)$ and $\phi_j^{\star T} \mathbf{J} \phi_i = \phi_j^T \mathbf{J} \phi_i^\star = 0$ $(\forall i \neq j)$(see [9]). However, the base is not normalized automatically after computation of the eigenproblem. We can calculate the weighting matrix as follows

$$\begin{aligned} \mathbf{\Psi} &= \mathbf{\Phi}^{\star T} \mathbf{J} \mathbf{\Phi} = \mathbf{\Phi}_q^{\star T} \mathbf{\Phi}_F - \mathbf{\Phi}_F^{\star T} \mathbf{\Phi}_q \\ \mathbf{\Psi}^\star &= \mathbf{\Phi}^T \mathbf{J} \mathbf{\Phi}^\star = \mathbf{\Phi}_q^T \mathbf{\Phi}_F^\star - \mathbf{\Phi}_F^T \mathbf{\Phi}_q^\star \end{aligned} \tag{20}$$

The matrices $\mathbf{\Psi}, \mathbf{\Psi}^\star$ are diagonal and satisfying $\mathbf{\Psi}^\star = -\mathbf{\Psi}^T$. Thus, we can normalize the wave base by calculating a matrix $\mathbf{T} = \mathbf{\Psi}^{1/2}$ where $\mathbf{T}$ is a diagonal matrix with the diagonal equals to the square root of the diagonal of $\mathbf{\Psi}$. The normalized wave base is presented by $\mathbf{\Phi T}$ and $\mathbf{\Phi}^\star \mathbf{T}$.

2.2 Wave decomposition

We can decompose each vector of equation (9) in this wave base as follows

$$\begin{aligned} \mathbf{u}^{(n)} &= \mathbf{\Phi} \mathbf{Q}^{(n)} - \mathbf{\Phi}^\star \mathbf{Q}^{\star(n)} \\ \mathbf{b}^{(n)} &= \mathbf{\Phi} \mathbf{Q}_E^{(n)} - \mathbf{\Phi}^\star \mathbf{Q}_E^{\star(n)} \end{aligned} \tag{21}$$

where $\mathbf{Q}^{(n)}, \mathbf{Q}^{\star(n)}$ are the wave amplitudes of $\mathbf{u}^{(n)}$ and $\mathbf{Q}_E^{(k)}, \mathbf{Q}_E^{\star(k)}$ are the wave amplitudes of the external loads on the intermediate substructures $\mathbf{b}^{(n)}$.

Remark: the wave decomposition in equation (21) is different to usual expression for WFE by the minus sign on the right to left waves. The avantage of this expression is that we can calculate directly the wave amplitudes by using the symplectic orthogonality of the wave base as the following

$$\begin{aligned} \mathbf{Q}^{(n)} &= \mathbf{\Phi}^{\star T} \mathbf{J} \mathbf{u}^{(n)}, \quad \mathbf{Q}^{\star(n)} = \mathbf{\Phi}^T \mathbf{J} \mathbf{u}^{(n)} \\ \mathbf{Q}_E^{(n)} &= \mathbf{\Phi}^{\star T} \mathbf{J} \mathbf{b}^{(n)}, \quad \mathbf{Q}_E^{\star(n)} = \mathbf{\Phi}^T \mathbf{J} \mathbf{b}^{(n)} \end{aligned} \tag{22}$$

By substituting equation (10) into equation (22), we obtain

$$\begin{aligned}\boldsymbol{\Phi}^{\star T}\mathbf{J}\mathbf{b}^{(n)} &= \left(\boldsymbol{\Phi}_q^{\star T}\mathbf{D}_{fI} - \boldsymbol{\Phi}_F^{\star T}\mathbf{D}_{qI}\right)\mathbf{F}_I^{(k)} - \boldsymbol{\Phi}_q^{\star T}\mathbf{F}_{\partial R}^{(k)} \\ \boldsymbol{\Phi}^{T}\mathbf{J}\mathbf{b}^{(n)} &= \left(\boldsymbol{\Phi}_q^{T}\mathbf{D}_{fI} - \boldsymbol{\Phi}_F^{T}\mathbf{D}_{qI}\right)\mathbf{F}_I^{(k)} - \boldsymbol{\Phi}_q^{T}\mathbf{F}_{\partial R}^{(k)}\end{aligned} \tag{23}$$

In addition, we have the relation between the $\boldsymbol{\Phi}_q$ and $\boldsymbol{\Phi}_F$ as follows (see [**?**])

$$\begin{aligned}\boldsymbol{\Phi}_F &= \mathbf{D}_{RR}\boldsymbol{\Phi}_q + \mathbf{D}_{RL}\boldsymbol{\Phi}_q\boldsymbol{\mu}^{\star} = -\left(\mathbf{D}_{LL}\boldsymbol{\Phi}_q + \mathbf{D}_{LR}\boldsymbol{\Phi}_q\boldsymbol{\mu}\right) \\ \boldsymbol{\Phi}_F^{\star} &= \mathbf{D}_{RR}\boldsymbol{\Phi}_q^{\star} + \mathbf{D}_{RL}\boldsymbol{\Phi}_q^{\star}\boldsymbol{\mu} = -\left(\mathbf{D}_{LL}\boldsymbol{\Phi}_q^{\star} + \mathbf{D}_{LR}\boldsymbol{\Phi}_q^{\star}\boldsymbol{\mu}^{\star}\right)\end{aligned} \tag{24}$$

By combining equations (22) and (23) into equation (24), we obtain

$$\begin{aligned}\mathbf{Q}_E^{(k)} &= \left[\left(\boldsymbol{\mu}\boldsymbol{\Phi}_q^{\star T}\mathbf{D}_{LI} + \boldsymbol{\Phi}_q^{\star T}\mathbf{D}_{RI}\right)\mathbf{F}_I^{(k)} - \boldsymbol{\Phi}_q^{\star T}\mathbf{F}_{\partial R}^{(k)}\right] \\ \mathbf{Q}_E^{\star(k)} &= \left[\left(\boldsymbol{\mu}^{\star}\boldsymbol{\Phi}_q^{T}\mathbf{D}_{LI} + \boldsymbol{\Phi}_q^{T}\mathbf{D}_{RI}\right)\mathbf{F}_I^{(k)} - \boldsymbol{\Phi}_q^{T}\mathbf{F}_{\partial R}^{(k)}\right]\end{aligned} \tag{25}$$

Equation (25) show that the wave amplitude of external loads on one substructure can be calculated directly from its loads and it does not depend on the other substructures.

Now we will calculate the amplitude from the wave amplitudes $\{\mathbf{Q}^{(n)}, \mathbf{Q}^{\star(n)}\}$. By replacing equation (21) with $n = 0$ into equation (11), we obtain

$$\mathbf{u}^{(n)} = \boldsymbol{\Phi}\mathbf{Q}^{(n)} - \boldsymbol{\Phi}^{\star}\mathbf{Q}^{\star(n)} = \boldsymbol{\Phi}\boldsymbol{\mu}^{n}\mathbf{Q} - \boldsymbol{\Phi}^{\star}\boldsymbol{\mu}^{\star n}\mathbf{Q}^{\star} + \sum_{k=1}^{n}\boldsymbol{\Phi}\boldsymbol{\mu}^{n-k}\mathbf{Q}_E^{(k)} - \boldsymbol{\Phi}^{\star}\boldsymbol{\mu}^{\star n-k}\mathbf{Q}_E^{\star(k)} \tag{26}$$

Then, by substituting equation (22) into the aforementioned equation, we obtain

$$\begin{aligned}\mathbf{Q}^{(n)} &= \boldsymbol{\mu}^{n}\left(\mathbf{Q} + \sum_{k=1}^{n}\boldsymbol{\mu}^{\star k}\mathbf{Q}_E^{(k)}\right) \\ \mathbf{Q}^{\star(n)} &= \boldsymbol{\mu}^{\star n}\left(\mathbf{Q}^{\star} + \sum_{k=1}^{n}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{\star(k)}\right)\end{aligned} \tag{27}$$

In a similar way, by combining equations (21) into equation (12), we obtain the following result

$$\begin{aligned}\mathbf{Q}^{(-n)} &= \boldsymbol{\mu}^{\star n}\left(\mathbf{Q} - \sum_{k=0}^{n-1}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{(-k)}\right) \\ \mathbf{Q}^{\star(-n)} &= \boldsymbol{\mu}^{n}\left(\mathbf{Q}^{\star} - \sum_{k=0}^{n-1}\boldsymbol{\mu}^{\star k}\mathbf{Q}_E^{\star(-k)}\right)\end{aligned} \tag{28}$$

Equations (27) and (28) present the relations between the wave amplitudes of the external loads and the amplitudes $\{\mathbf{Q}, \mathbf{Q}^{\star}\}$ of $\mathbf{u}^{(0)}$. In the next section, we will develop the wave analysis by using this result and the boundary condition for an infinite periodic track.

3 ANALYSIS OF A COMPLETE RAILWAY TRACK

3.1 Response of an infinite periodic railway track

We consider a railway without defects as show in Figure 1. The track is an infinite periodic structure subjected to moving dynamic loads which can be different from one period to another. We will find the response by using the bounded condition.

By substituting equations (27) and (28) into equation (21), we obtain

$$\begin{aligned}
\mathbf{u}^{(n)} &= \boldsymbol{\Phi}\boldsymbol{\mu}^{n}\left(\mathbf{Q}+\sum_{k=1}^{n}\boldsymbol{\mu}^{\star k}\mathbf{Q}_E^{(k)}\right)-\boldsymbol{\Phi}^{\star}\boldsymbol{\mu}^{\star n}\left(\mathbf{Q}^{\star}+\sum_{k=1}^{n}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{\star(k)}\right)\\
\mathbf{u}^{(-n)} &= \boldsymbol{\Phi}\boldsymbol{\mu}^{\star n}\left(\mathbf{Q}-\sum_{k=0}^{n-1}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{(-k)}\right)-\boldsymbol{\Phi}^{\star}\boldsymbol{\mu}^{n}\left(\mathbf{Q}^{\star}-\sum_{k=0}^{n-1}\boldsymbol{\mu}^{\star k}\mathbf{Q}_E^{\star(-k)}\right)
\end{aligned} \tag{29}$$

For a damped structure, $\|\boldsymbol{\mu}\|<1$ and $\|\boldsymbol{\mu}^{\star}\|>1$ (see [8]). Therefore, we have $\boldsymbol{\mu}^{n}\to 0$ and $\boldsymbol{\mu}^{\star n}\to\infty$ when n tends to infinity. Therefore, in order to get $\mathbf{u}^{(n)}$ and $\mathbf{u}^{(-n)}$ in equation (29) satisfying the bounded condition (14), the coefficients corresponding to $\boldsymbol{\mu}^{\star n}$ must tend to zeros when $n\to\infty$. That means

$$\mathbf{Q}=\sum_{k=0}^{\infty}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{(-k)},\quad \mathbf{Q}^{\star}=-\sum_{k=1}^{\infty}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{\star(k)} \tag{30}$$

By substituting the aforementioned equation into equation (21) with $n=0$, we obtain

$$\begin{aligned}
\mathbf{q}^{(0)} &= \boldsymbol{\Phi}_q\sum_{k=0}^{\infty}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{(-k)}+\boldsymbol{\Phi}_q^{\star}\sum_{k=1}^{\infty}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{\star(k)}\\
\mathbf{F}^{(0)} &= \boldsymbol{\Phi}_F\sum_{k=0}^{\infty}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{(-k)}+\boldsymbol{\Phi}_F^{\star}\sum_{k=1}^{\infty}\boldsymbol{\mu}^{k}\mathbf{Q}_E^{\star(k)}
\end{aligned} \tag{31}$$

Equation (31) is the expression of the response of the substructure at $n=0$. For the others substructures $n\neq 0$, we can calculate the response by using equation (29). There is another way to calculate the responses $\mathbf{u}^{(n)}$ by translating the reference origin and using again the formulation (31).

3.2 Remarks

- We see that the response $\mathbf{u}^{(0)}$ is the combination of two terms corresponding to the sum of left and right waves generated by the external forces from the two sides. If the structure is subjected by an external load at only one side of a period, the expressions in equation (31) have only one term and the eigenvalue $\boldsymbol{\mu}$ is exactly the rate of the wave amplitudes between the left and right boundary of one period. Therefore, the eigenvalues $\boldsymbol{\mu}$ plays a role as a **structural damping factor** of a periodic structure.

Table 1: Parameters of a periodically supported beam

Rail section mass (ρS)	kg/m	60
Rail stiffness (EI)	MNm^2	6.3
Distance of sleepers (l)	m	0.6
Block mass (M)	kg	100
Damping factor of rail pad (η_1)	MNsm^{-1}	1.97
Stiffness of rail pad (k_1)	MNm^{-1}	192
Damping coeff. under support (η_2)	MNsm^{-1}	0.17
Stiffness under support (k_2)	MNm^{-1}	26.4

- This method does not need to inverse any matrix, the responses can be calculated directly from the wave decompositions. Therefore, we have reduced the DOF of all structure to only one substructure.

- When the moving load is the same for all substructure, by combining equations (13) and (25) we obtain

$$\mathbf{Q}_E^{\star(n)} = \mathrm{e}^{\mathrm{i}\omega\frac{nl}{v}}\mathbf{Q}_E^{\star(0)}, \quad \mathbf{Q}_E^{(k)} = \mathrm{e}^{\mathrm{i}\omega\frac{nl}{v}}\mathbf{Q}_E^{(0)} \quad \forall n \tag{32}$$

  In addition, $\boldsymbol{\mu}$ is a diagonal matrix, we can use a formula of the geometric series $\sum_{k=0}^{\infty}(a\boldsymbol{\mu})^k = \frac{1}{1-a\boldsymbol{\mu}}$ provided that $\|a\boldsymbol{\mu}\| < 1$ (this is a diagonal matrix with the values calculated by the formulas in the expression). Therefore, we can rewritten equation (31) as follows

$$\begin{aligned}
\mathbf{q}^{(0)} &= \boldsymbol{\Phi}_q \frac{1}{1-\boldsymbol{\mu}\mathrm{e}^{-\mathrm{i}\omega\frac{l}{v}}}\mathbf{Q}_E^{(0)} + \boldsymbol{\Phi}_q^{\star}\frac{\boldsymbol{\mu}\mathrm{e}^{\mathrm{i}\omega\frac{l}{v}}}{1-\boldsymbol{\mu}\mathrm{e}^{\mathrm{i}\omega\frac{l}{v}}}\mathbf{Q}_E^{\star(0)} \\
\mathbf{F}^{(0)} &= \boldsymbol{\Phi}_F \frac{1}{1-\boldsymbol{\mu}\mathrm{e}^{-\mathrm{i}\omega\frac{l}{v}}}\mathbf{Q}_E^{(0)} + \boldsymbol{\Phi}_F^{\star}\frac{\boldsymbol{\mu}\mathrm{e}^{\mathrm{i}\omega\frac{l}{v}}}{1-\boldsymbol{\mu}\mathrm{e}^{\mathrm{i}\omega\frac{l}{v}}}\mathbf{Q}_E^{\star(0)}
\end{aligned} \tag{33}$$

- We can decompose the real loads of a train into dynamic and statique loads. Because the statique loads are constant, we can apply the formula (33) for this term and then apply the formula (31) for the dynamic loads.

4 NUMERICAL APPLICATIONS

Consider a periodically supported beam subjected to a constant moving load as shown in Figure 2, where the rail is modeled by Euler-Bernoulli beam and the support systems are the mass-springs. The beam is subjected to a constant moving load $Q = 100kN$.The parameters of the railway track are given in Table 1. Now we will compare the analytic solution [6] and the numerical method. From the finite element method with element type B21 in Abaqus, we obtain the dynamic stiffness matrix of the beam for one period of length l. In order to take into account the supports, we add the support dynamic stiffness into the beam stiffness matrix at the term in the diagonal corresponding to the DOF of the contact point between the beam and the spring-mass. Figure 3 shows a comparison

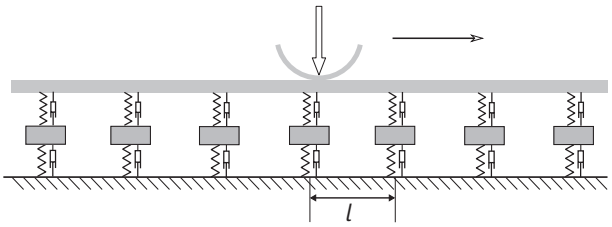

Figure 2: Periodically supported beam subjected to a moving load

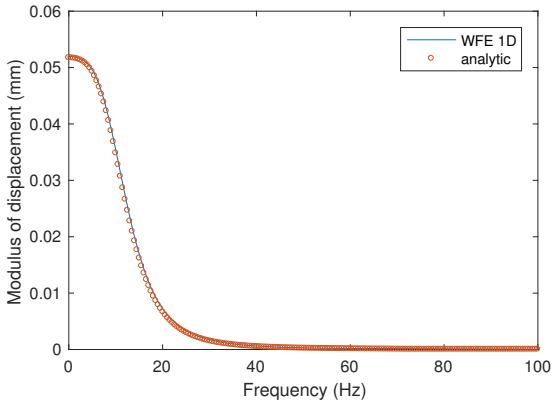

Figure 3: Response of the periodically supported beam by the analytical and numerical methods

of the analytic and numerical results with element B21 of size 1cm in Abaqus. In this example, the calculation times of the numerical method is almost the same time of the analytical method. We note that this result is for an infinite beam for the both two methods and it does not exist for the classical FEM. In addition, Figure 4 presents the structural damping factor $\boldsymbol{\mu}$.

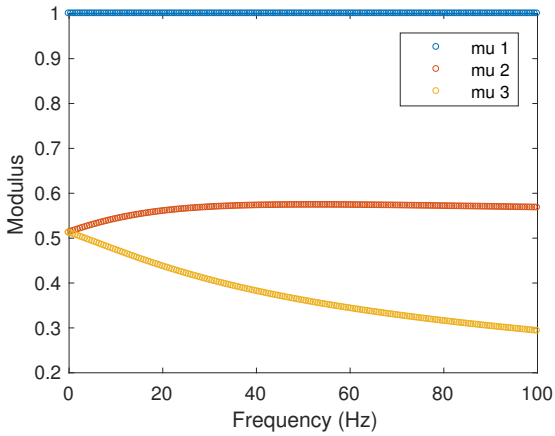

Figure 4: Structural damping factor of a railway track

Moreover, the numerical method permits to calculate the response of the track subjected to dynamic forces as shown in Figure 5. Here we consider a random dynamic force occurs at one point on the track with an amplitude $Q_{dyna} = 100$kN in an frequency bandwidth $[25 - 50]$Hz. The track response is the sum of the response to the static load calculated by equation (33) and the dynamic load calculated by equation (31).

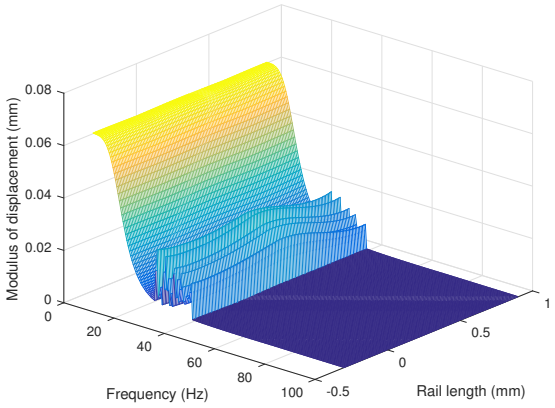

Figure 5: Response of the track to a dynamic load

Now we consider an example of a non-ballasted railway track where the supports contains a rail pad, a concrete block and an elastic pad under the block. All the component of the support and the concrete slab are simulated by the element finit method with the mesh shown in Figure 6. In this model, we have 16.075 elements C3D8R. The base of the slab is fixed and the track is subjected by moving force $Q = 100$kN at a row of nodes on the rail.

Figure 7 presents the response of the loaded point by WFE for beam and 3D models and the analytic result. The calculation time for 3D model is 21.6h and for other model is about 0.2s. We see that the responses by different methods are coherent. The 3D model response has noise because it cause by the error of the eigenvalue calculation.

5 CONCLUSION

By using the wave finite element method, we demonstrate that the wave amplitude at the boundary of one period of the track can be represented by a sum of the wave amplitude which corresponds to the moving loads. This characteristics comes from the bounded condition of the infinite periodic structure. This method permits to reduce the DOF of the railway track to only one track period while remaining all the dynamic load.

A Lattice Green Function Method for Atomistic/Continuum Coupling: Theory and Data Sparse Implementation

ABSTRACT

Treating atoms individually in material science applications comes along with high computational cost with increasing simulation size. However, many problems require atomic scale resolution only in small parts of the computational domain to resolve the nonlinear behavior of isolated defects, e.g. crack tips, dislocations, voids etc. Commonly these problems are treated using homogeneous Dirichlet conditions on the outer boundary (or the elastic field of the defect). However, if the Green function of the defect is long range, the problem sample has to be sufficiently large to reach a desired accuracy. In the 1970's Sinclair and co-workers proposed so-called flexible boundary conditions which minimize inhomogeneous forces appearing in the pad domain after each atomistic relaxation by means of lattice Green functions [1]. In its original form the method is of O(NM), where N and M are the number of pad and real atoms, respectively, which becomes quickly unfeasible with increasing problem size. Here, we show that Sinclair's incremental update equation can be shown to be equivalent to a gradient descent iteration with respect to a weighted inner product space which converges to a discrete boundary method (DBM) analog to the boundary integral equation for exterior PDE's. In order to overcome the bottleneck of memory consumption we exploit the fact that the boundary matrices can be represented as hierarchical matrices [2]. Starting from the coupled atomistic/DBM problem we construct a fast and memory efficient monolithic solver which we have integrated into the open source atomistic code LAMMPS. We outline the efficiency of the proposed method for various test cases. We have recently proposed a simplified solution procedure for a novel coupled atomistic and discrete dislocation method in 3d by detecting dislocations in the entire atomistic system and subsequently using the displacement field of the complete dislocation network as a boundary condition for the atomistic problem [3]. While being accurate and simple to implement, this method is impracticable for general problems involving other types of defects. With our new DBM it becomes possible to embed moderately large atomistic domains in infinite continua. We present numerical examples for a hybrid dislocation bow-out in an (effectively) infinite medium. References [1] Sinclair, J. Forecasting Sea Ice Movement in the Arctic Basin Using the Discrete Element Method

Taylor Hodgdon*, Arnold Song**, Matthew Parno***, Brendan West****, Devin O'Connor*****

ABSTRACT

The global climate is rapidly changing and is especially amplified in the Arctic due to the diminishing sea ice cover. As the Arctic warms and conditions change, the assumptions and mechanical models that govern the forecast tools are also changing. The majority of current sea ice models use a continuum approach that typically use constitutive models that homogenize and parameterize processes that occur over relatively short length scales. For example, pressure ridges and fractures typically have widths on the order of tens of meters, in contrast to grid length scales on the order of kilometers in most sea ice models. We present work that uses the discrete element method (DEM) to examine mechanical processes, such as pressure ridging, at appropriate length scales using realistic floe geometries with spatially varying mechanical properties. This model, coupled with a workflow to assimilate remotely sensed data allows us to better estimate sea ice parameters and improve larger scale model parameterizations.

Continued Evolution of a Part-scale Finite Element Model for Selective Laser Melting at LLNL

Neil Hodge*, Rishi Ganeriwala**, Robert Ferencz***

*Lawrence Livermore National Laboratory, **Lawrence Livermore National Laboratory, ***Lawrence Livermore National Laboratory

ABSTRACT

Selective Laser Melting (SLM) is a manufacturing process which can realize significant benefits over traditional manufacturing processes, including significantly shortened time between design and manufacture of parts, and the ability to create parts with much more geometric complexity than has previously been tenable, or in some cases, even possible. However, the extreme sensitivity of the results to input parameters results in a process that is difficult to predict, and thus control. Indeed, it is not uncommon for the resulting parts to vary significantly from the desired geometry, and have associated residual stresses, due to the influence of extreme and inhomogeneous thermal gradients. The SLM process is difficult to model for several reasons, including the complex, dynamic physical phenomena, as well as its severely multiscale character. The current presentation will describe ongoing work within the parallel, implicit finite element code Diablo, toward several goals: (1) addition of new, and improvement of existing, physics, and (2) improvement of the throughput of simulations, while simultaneously keeping degradation of the solution accuracy to a minimum.

A New Class of Generalized Finite Element Spaces for Problems with Immersed Interfaces

Susanne Hoellbacher*, Gabriel Wittum**

*ECRC, King Abdullah University of Science and Technology, **ECRC, King Abdullah University of Science and Technology

ABSTRACT

For applications like multiphase flow, free surface flow or diffusion problems with discontinuous density, interface forces or fluxes arise on free boundaries and the location of the boundary changes in time. Instead of mesh adaptation or the introduction of artificial forces we follow the idea of adapted finite element spaces on elements cut by the immersed interface. The proposed spaces generalize the idea of balancing fluxes along a surface which essentially characterizes and constitutes a finite volume formulation. The derivation of the generalized spaces is inspired by the Petrov-Galerkin weak formulation of the finite volume method. Within a finite volume formulation the boundary fluxes naturally arise. As a consequence, the derived spaces similarly take the shape of the boundaries directly into account and the proposed spaces are well suited for the imposition of boundary conditions on immersed boundaries. Furthermore, the generalized finite element spaces get employed to the usual continuous Galerkin formulation. Therefore, the discrete system is symmetric and intrinsically stable. In particular, unlike in most DG formulations, there is no need for interior penalization in order to guarantee stability. Finally, we will show that the spaces obey even local conservation laws due to their relation to the finite volume formulation. As numerical examples, we consider diffusion problems and multiphase flow problems such as particle-fluid and gas-fluid mixtures. Regarding the special case of particle-fluid flow, a typical issue are spurious oscillations due to a bad approximation of the pressure near the interface. Our computations show, that the spurious pressure oscillations were eliminated by the new method without having to introduce interior penalty terms. The results therefore demonstrate that the adapted spaces describe the physics of the discrete interface appropriately.

ABSTRACT

We present recent advances in methodology and applications of our framework for simulation of turbulent flow and fluid-structure interaction. On the foundation of stabilized finite element methods and a posteriori error estimation, we have developed an approach to turbulence simulation where no model resolution is set a priori and unresolved scales are not explicitly modelled, but instead the resolution of the model is determined as part of the simulation by adaptive mesh refinement and the finite element approximation converges to a weak solution of the Navier-Stokes equations with respect to selected functionals, such as lift and drag in an application of aerodynamics, for example [1]. In this talk we present new developments with regards to the underlying mathematical theory, a posteriori error estimation, and the mesh adaption algorithms, in particular with respect to high performance computing. We also present recent advances of the monolithic approach to fluid-structure interaction we have developed, where the fundamental conservation laws are formulated for the unified continuum of all phases in the problem, which leads to a robust method for fluid-structure interaction, including contact mechanics. The methods are implemented in the open source software FEniCS-HPC [2], and we present new results from applications in flight aerodynamics, wind turbines, and patient-specific heart simulations [3]. Physiological and Pathological Cortical Thickness Variations

Maria Holland*, Antonio Hardan**, Alain Goriely***, Ellen Kuhl****

*University of Notre Dame, **Stanford University, ***University of Oxford, ****Stanford University

ABSTRACT

The brains of humans and many other mammals are characterized by deep wrinkles and folds in the surface layer, the cortex. The thickness of this cortical layer is an important biomarker for a wide variety of neurological disorders, and alterations in cortical thickness have been associated with neurodevelopmental disorders including epilepsy, schizophrenia, and Autism Spectrum Disorders (ASD) [1]. However, cortical thickness is significantly heterogeneous throughout the brain, featuring a marked regional asymmetry, with thicker peaks (called gyri) and thinner valleys (called sulci). It has been suggested that this is the result of localized heterogeneities in growth, but our findings [2] indicate that this thickness difference appears in non-growing materials as well. Here we show that a simple homogeneous bilayered system of a growing layer on an elastic substrate universally bifurcates into a spatially heterogeneous system with thicker peaks and thinner valleys. We present a combined experimental, computational, and analytical approach that illustrates the origin and evolution of this pattern as a consistent instability phenomenon in soft materials, likely related to the strong dependency on boundary conditions and loading in the instability behavior of soft materials [3]. In light of this finding, we use the regional gyral-sulcal cortical thickness ratio as a tool to investigate atypical cortical folding and structure in individuals on the ASD spectrum. Using medical imaging data from the Autism Brain Imaging Data Exchange as well as a study of twins with and without ASD, we analyze differences in cortical thickness variation between diagnosis groups and explore potential biomechanical explanations for the evolution of these patterns. Our findings support previous work suggesting that mechanics plays an important role in the development of the brain, showing that this characteristic pattern of thickness variation in the cortex can be explained at least partly by forces arises during cortical folding. Evaluation of Mesh-Control Techniques for FSI Analysis Handling Large Deformation in Structural and Fluid Domains

Giwon Hong*, Tomonori Yamada**, Naoto Mitsume***, Shinobu Yoshimura****

*The University of Tokyo, **The University of Tokyo, ***The University of Tokyo, ****The University of Tokyo

ABSTRACT

Fluid-structure interaction (FSI) analysis has been used to clarify design variables related to FSI phenomena. One application is the analysis of flapping motions to improve flapping wing aerodynamics and to design optimized models for micro air vehicles (MAVs) in morphology and kinematics. A flexible wing is deformed nonlinearly during flapping cycles, so it is important to track its surface properly and to get its aerodynamic data accurately in terms of FSI analysis. We have developed the three-dimensional FSI analysis system employing partitioned iterative coupling methods [1], which utilize existing solvers: a parallel FEM flow solver FrontFlow/blue and a parallel FEM structure solver ADVENTURE_Solid. The system successfully analyzed simple flapping motions. To handle a flexible structure is still a challenging issue in FSI analysis, since the large deformation in both structural and fluid domains follows when the structure moves excessively. Consequently, mesh distortion occurs and the degenerated shape of the domains makes FSI analysis failed. Some way such as remeshing might be a good option to continue the analysis. However, we have researched on the analysis depending on initial data in order to maximize the efficiency of parallel computing. In this research, we focus on the way to deal with the deformation of a fluid domain. We aim to make FSI analysis progress by controlling a mesh in a proper way, even if the large deformation and mesh distortion follow. In order to improve the distortion, fluid meshes are partitioned in different ways, and mesh-control techniques such as SEMMT [2] are examined to control those meshes. We also intend to keep the mesh resolution near the interface between two domains. Then, we evaluate the difference of analyses that each mesh-control technique is applied for. Finally, we propose improved mesh-control techniques to contribute the stability of FSI analysis. References [1] T. Yamada, G. Hong, S. Kataoka, S. Yoshimura. Key words: solar power plant, floating body, connector beam, hydroelastic analysis, frequency-domain analysis, time-domain analysis

Abstract. The hydrodynamic performance of a floating solar energy converter system in waves is analyzed considering elastic behaviors of connector structures in this study. The converter system is composed of hundreds of floating concrete blocks to support photovoltaic modules. The slender elastic connector structure combines the floaters into a large unit system. The floating solar power converter system keeps its position by using mooring system. To assure structural integrity as well as operability of the system in waves, both the frequency-domain and time-domain approaches are adopted to analyze hydroelastic behaviors of the system. In numerical formulation, HOBEM (Higher Order Boundary Element Method) is applied to floating body part and FEM (Finite Element Method) was applied to connector beams and mooring lines. HOBEM is a highly accurate and efficient method in analysis of multi-body hydrodynamic interactions. The frequency domain analysis is powerful in parametric design stage because it provides relatively simple and fast calculations. In specific cases, time domain analysis is required to see the results in detail for transient behavior coupled with mooring lines, and for nonlinear large amplitude and low frequency motion responses due wave drift forces under harsh environments. In the present study, the frequency-domain analysis is implemented which is useful for structural optimization design process while the time domain analyses is implemented useful for extreme structural and mooring responses. In addition to discussions on structural safety of the system, an efficient algorithm for reduction of computational burden considering a few thousand floaters of multiple MW class floating solar power plants is discussed by comparison with a fully direct FEM formulation and Guyan reduction scheme for connector structures as well.

1. INTRODUCTION

Due to recent global climate change, a number of Asian and North American countries are focusing on increasing renewable energy portion for sustainable development of electric power and reduction of CO2 to suppress global warming. Solar electric power has been emerging as a dominating position, competing with an existing crown chair of wind energy. Both energy resources require a huge area to obtain commercially viable large-scale production. Ironically, those resources induce unwanted environmental pollutions such as noise, views, shade and reflections of sun light, which result in negative effects on the ecology of human and animal worlds. The first simple solution to resolve this problem was to place those facilities at remote area, far from the place with high population of human beings, even though the negative impacts on animal still exist. For photovoltaic electric power generation, the portion of floating solar power generation has been increasing since 2007 due to its advantages coming from using void space. Using void space reduced legal conflicts with nearby residents in view of sociology and enhanced efficiency is possible by virtue of uniformly flat area and cooling effect thanks to surrounding cooling water in terms of technology. There still exists some considerations associated with technical challenge for extension to sea areas beyond inland water surface, in terms of cost down and assurance of safety. Such an advantage is more effective in countries with limited flat and void space such as Korea and Japan. A preliminary study on floating solar power system by Hong et al. (2017) showed positive perspectives on a large scale floating solar power system in the sea region by adopting hydroelastic approach in design and analysis of floaters and supporting frame structures.

Most of ocean renewable energy is affordable only when an appropriate structure is provided for assurance of safety as well as economic efficiency considering characteristics of ocean renewable energy source and environmental conditions of the site.

The floating solar power system can be modelled as a mass-spring-damper system for design and analysis purpose. The system is composed of multiple floaters supporting photovoltaic cells, grillage structures combining multiple floaters into one large unit structure, and mooring system providing restoring forces to keep the position of floating structures within a target location. For huge floating structures, the design concept adopting hydroelasticity is useful for finding an optimal structural solution for assurance of safety under harsh environment as well as economy.

In design of floating solar power system, in many cases, engineers calculate hydrodynamic responses of unit modules for simplicity. However, Hong et al.(2017) found that total module need to be analyzed to get more reliable results because the responses are different as shown in Fig. 1 which was referred from Hong's previous research [1]. As seen in the figure, the response curves show different peak locations and stress levels because the two different sized structure have different mass and spring, which resulted in different natural frequencies and resonant behaviors. This result clearly demonstrated why the whole structure should be analyzed because the analysis result for a small unit gives more conservative estimation than that of the whole structure.

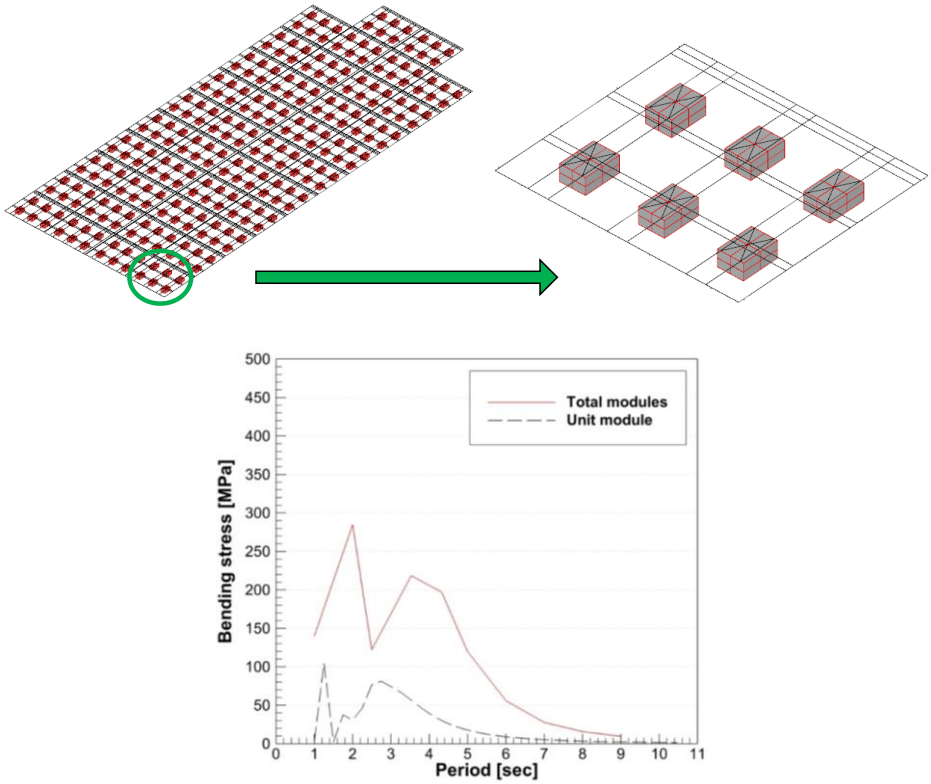

Fig. 1 Comparison of total module and unit module in hydrodynamic responses of floating solar power plant

In the present study, the hydroelastic behaviors of a floating solar energy converter system in waves is analyzed. The converter system is composed of hundreds of floating concrete blocks to support photovoltaic modules. The slender elastic connector structure combines the floaters into a large unit system. Both the frequency-domain and time-domain approaches are implemented in hydroleastic analysis. The frequency domain analysis is powerful in parametric design stage because it provides relatively simple and fast calculations. In specific cases, time domain analysis is required to see the results in detail for transient behavior coupled with mooring lines, and for nonlinear large amplitude and low frequency motion responses due wave drift forces under harsh environments. In this study, frequency-domain and time domain analyses results were compared with each other to verify both results and investigate transient effects and nonlinearity. In addition to discussions on structural safety of the system, an efficient algorithm for reduction of computational burden considering a few thousand floaters of multiple MW class floating solar power plants is discussed by comparison with a fully direct FEM formulation and Guyan reduction scheme for connector structures as well.

2. FLOATING SOLAR POWER PLANT

The developed solar power plant system is comprised of multiple floating bodies and connectors. Floating bodies were made of concrete blocks and they support solar energy generation system on topside. The blocks were connected with steel profile beams and mooring lines are attached to the beams to keep the position. Fig. 2 shows geometric layout of the plant system. Shape of one concrete block and the section shape of the connector beams are shown in Fig. 3. The mechanical properties of floaters, connectors and mooring lines were summarized in Table 1.

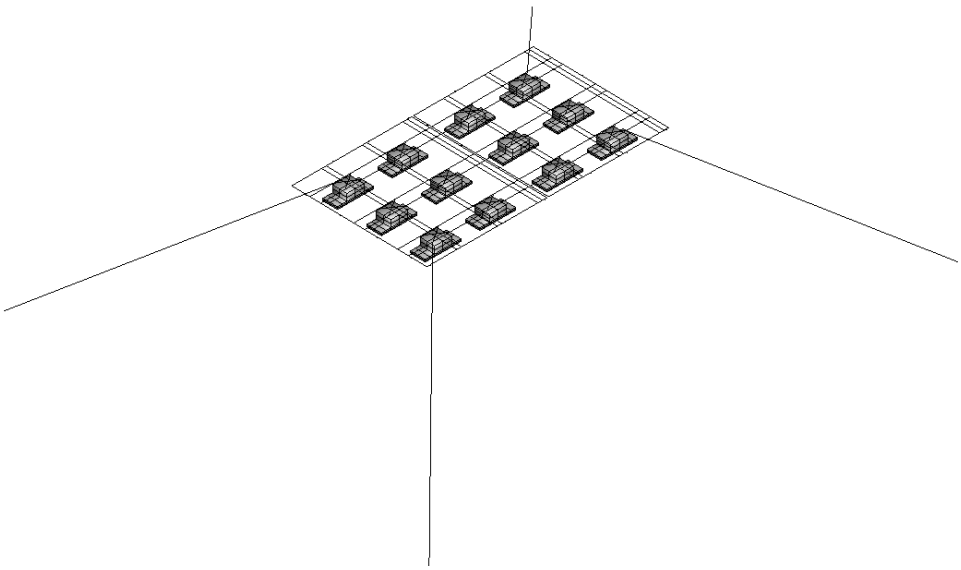

Fig. 2 Layout of floating solar power plant system

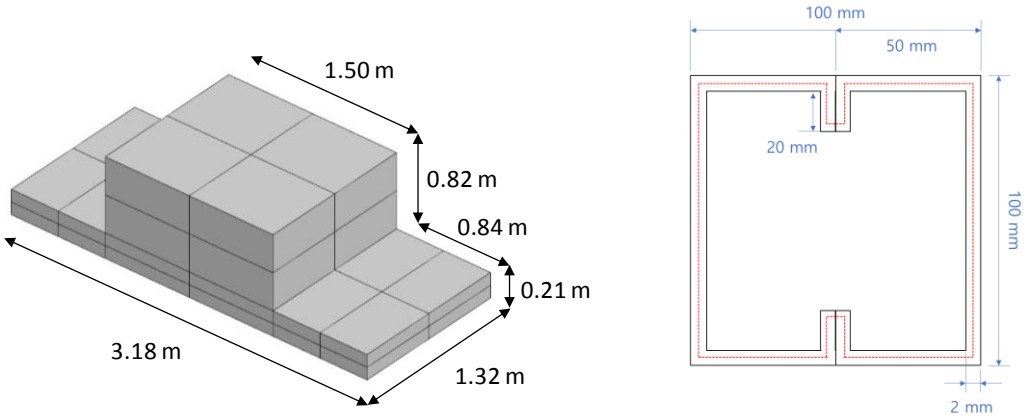

Fig. 3 Floating concrete block and section profile of connector beam

Table 1 Particulars of floater and connector

Part	Property	
Floating bodies	Type	Concrete block
	Breadth×Length×Depth×Draft	1.32m×3.18m×1.03m×0.84m
	Displacement	2.128896 ton
Connectors	Type	Steel profile beam
	Axial stiffness (EA)	1.869×10^8 N
	Bending stiffness (EI)	294,580 N-m^2
	Torsion stiffness (GJ)	121,810 N-m^2
	Mass per length (m)	7.12 kg/m
Mooring lines	Type	Steel spring
	Spring constant (K)	849.166 N/m

Water depth of the target site is set to be 10 m. Waves and drifts effects were considered for main environmental forces. Wave frequencies of 0.05 ~ 2π rad/s were considered and wave height(H) was assumed to be λ/10 but not greater than 0.5 m. Heading angle of wave, β is considered for 0, 45 and 90 deg.

3. EQUATION OF MOTION

Hydroelastic equation of motions should be formulated and solved to analyze coupled responses of floaters, connectors and mooring lines in waves. Coupled equation can be expressed by (1) in frequency domain.

$$(-\omega^2[M_b+M_c]-i\omega[\ _b+\ _c]+[\ _b+\ _c])\{u(\omega)\}=\{f_w(\omega)\} \tag{1}$$

where $[M_b]$ is mass matrix for floating bodies including added mass effect, $[\ _b]$ is hydrodynamic damping matrix, $[\ _b]$ is restoring stiffness matrix of floating bodies, $\{f_w(\omega)\}$ is wave force vector, $\{u(\omega)\}$ is displacement vector for bodies, connectors and mooring lines. ω is wave frequency. This study applied HOBEM [2,3] to obtain added mass, hydrodynamic damping and wave forces because it provides highly accurate and efficient solution in the analysis of multi-body interactions. In (1), $[M_c]$ is mass matrix for connector beams and mooring lines, $[\ _c]$ is damping matrix, $[\ _c]$ is stiffness matrix and FEM [4] was applied to formulating connector beams and mooring lines. Frequency domain analysis is very fast because it calculates only steady-state amplitude of responses. It is also useful to see the responses versus frequencies rapidly. So it is usually employed in predesign stage. However, frequency analysis cannot review the transient responses including natural mode components. It neither can see the responses in mixed frequency forces such as drift force. In that case, time domain analysis is required and the equation of motions takes the form by (2).

$$[M_b+M_c]\{\ddot{u}(t)\}+[\ _b+\ _c]\{\dot{u}(t)\}+[\ _b+\ _c]\{u(t)\}=\{f_w(t)+f_d(t)\} \tag{2}$$

where $\{f_d(t)\}$ is force vector due to drift forces. This paper applied the method by Choi et al. [1] to calculate drift forces. Time domain analysis can review the transient or mixed components of responses. But, it is time consuming because it calculates time series of responses. Numerically stable time marching should be chosen in time domain analysis. This study applied the modified Newmark algorithm [5] in time marching.
If floating body part alone is a main concern in the analysis, simpler equation can be formulated by using Guyan reduction [6]. It takes the form.

$$(-\omega^2[M_b]-i\omega[\ _b]+[\ _b+\quad])\{u_b(\omega)\}=\{f_w(\omega)\} \tag{3}$$

where $\{u_b(\omega)\}$ is displacement for floating bodies and [ ] is reduced stiffness matrix due to effect by connectors and mooring lines. If stiffness matrix of connectors and mooring lines are partitioned with part B where floating bodies are attached and part A for otherwise

$$[\ _c]=\begin{bmatrix} & \\ & \end{bmatrix} \tag{4}$$

the equivalent reduced stiffness matrix is obtained by

$$[\quad]=[\quad]-[\quad][\quad]^{-1}[\quad] \tag{5}$$

Eq. (3) is simpler than (1) or (2). However, it cannot investigate responses in connectors or mooring lines. If stresses in connectors are main design concerns, (1) or (2) should be solved.

4. NUMERICAL ANALYSES AND DISCUSSIONS

The floating solar power system was analyzed by HOBEM and FEM described in section 3. Total HOBEM nodes for floating bodies are 888 and number of FEM nodes for connector beams are 664. Displacements at the floating body and stresses in connector beams were investigated and the results were compared for frequency and time domain analyses. Displacements at floating body no. 1 and stresses at connector element no. 35 in β=45 deg were compared because the maximum responses were observed at the condition. Their locations are shown in Fig. 4.
Analysis results are summarized in Figs. 5~15. Fig. 5 compares frequency domain analysis with Guyan reduction (Eq. (3)) and time domain analyses (Eq. (2)) for floating body motions. Transient responses due to long period drift motions are well shown in time domain analysis but it cannot be shown in frequency domain analysis. However, steady state responses are well agreed. Eq. (3) is applicable if floating body motions alone are main design parameters. However, connector stresses as well as floating body motions are key design factors in the floating system in this study. So, body-connector coupled analysis are required. Therefore, Eqs.

(1) and (2) were mainly applied in this study and the other figures are comparing Eqs. (1) and (2). Fig. 6 shows steady-state amplitude of connector stress versus wave period. Bigger stresses are shown at two peaks. The first peak is related with natural bending period of connector beam. It is 1.18 sec. The second peak is due to natural heave period of floating body. It is 3.22 sec. It is shown that frequency and time domain results agree well. Frequency domain analysis is faster than time domain analysis because it only calculates amplitude and phase of responses. For example, cpu time was 52.656 sec in time domain analysis of one frequency case in this example study with simulation time=400 sec with time step=0.1 sec. While, cpu time was merely 0.098 sec for one frequency case in frequency domain analysis. So, the frequency responses curve like Fig. 6 is easily obtained from frequency domain analysis. Figs. 7~9 compare time series of connector stresses for frequency and time domain analyses. Some differences are shown in transient part between frequency and time domain analyses because the effect by natural bending mode or drift force are included in the transient part. Time domain analysis can describe the transient behavior but frequency domain cannot. However, good agreements are shown in the steady-state stresses because transient components are damped out in the stead-state part.

Fig. 10 summarizes displacements at floating body versus wave period. The peak values in x, y and z displacements are related with natural periods of surge, sway, heave, respectively. They are 27.06 sec, 27.06 sec and 3.22 sec. Figs. 11~13 compare time series of displacements at floating body for frequency and time domain analyses. Slowly varying displacements due to drift forces or transient displacements due to natural modes can be investigated in time domain analyses but they cannot be in frequency domain analysis. However, steady-state amplitude are well agreed between time domain and frequency domain analyses.

Higher wave was analyzed to see the variation of connector stress and mooring line tension versus wave heights. Figs. 15 and 16 are the results. It is shown that connector stress and mooring line tension linearly increase for wave heights due to negligible drift effects at that wave period

5. CONCLUSIONS

The hydroelastic behaviors of a floating solar energy converter system in waves has been analyzed both in frequency-domain and time-domain. Guyan reduction scheme for connector structures also has been implemented for application to huge structures which can cover tens of MW structures. From a series of systematic numerical investigations of the results from three different approaches, the following conclusions are drawn.

- The results of frequency-domain analysis were verified by those of time-domain analysis. The motion RAO and stress RAO from both the frequency-domain analysis and time-domain analysis showed equivalent results in steady state while the time-domain results showed transient effect and drift motion effect as well. It was confirmed that the frequency domain

analysis results provide a variety of beam natural mode response as well. The computational time of the frequency-domain analysis was more than 500 times than the time-domain when the simulation time set to be 400sec. in full scale, which corresponds to 40 cycles when wave period is assumed to be 10 seconds.

- However, frequency domain analysis cannot review transient or slowly varying responses due to natural mode behavior or drift forces. They can be observed by time domain analysis.
- It was confirmed that Guyan reduction results gave same motion response as the frequency-domain analysis results. This implies Guyan reduction approach can give first screening information of a very huge structures because vertical mode motion correlates very well with stress RAO curves. But, we should be careful for using the Guyan reduction approach as the first screening tool because the Guyan reduction results cannot resolve beam natural model response.
- Further numerical analysis for a real huge floating solar power system is needed for final decision of the present three steps approach for analysis of the floating solar power plant.

A Modification of the Multi-step Optimisation of Variable Stiffness Laminates for Manufacturable Design

Zhi Hong*, Sergio Turteltaub**, Daniël Peeters***

*Delft University of Technology, **Delft University of Technology, ***University of Limerick

ABSTRACT

A commonly-used method for the optimisation of variable stiffness laminates involves a three-step procedure, namely (1) optimising the laminate in terms of lamination parameters, (2) retrieving the fiber angles and (3) constructing the fi ber path, sequentially[1]. To control the fiber steering in each layer of the laminate, manufacturing constraints, which control the maximum curvature of the fi ber angles, need to be considered[2]. Traditionally, manufacturing constraints have been imposed at the second step in terms of controlling the fi ber path curvature. In that case, the constraints affect the design, which typically results in a loss of performance between the optimal results from the fi rst and the second step. In the present work, we propose a scheme to include the manufacturing constraints directly at the fi rst step by taking gradient constraints on the lamination parameters and perform a comparative analysis between the present and the previous method. We test our method in several numerical cases to minimize the compliance of variable stiffness laminate with in-plane loads and compare the results from the existing design method. The initial numerical results show that our method can generate manufacturable designs and bridge the gaps of the performance loss between the first and second steps. Furthermore, the computational performance can also be enhanced simultaneously due to the reduced number of gradient constraints. One limitation of the proposed scheme is that the maximum curvature of the fiber angle is not controlled precisely, which may result in a higher compliance. Therefore, there should be a trade-off when making a decision between enforcing the constraints a priori or a posteriori. Computer Simulation of Glasses under Shear: From the Onset of Flow to Shear Banding

Juergen Horbach*, Gaurav Shrivastav**, Pinaki Chaudhuri***, Mehrdad Golkia****

*University of Duesseldorf, Germany, **TU Berlin, Germany, ***The Institute of Mathematical Sciences, Chennai, India, ****University of Duesseldorf, Germany

ABSTRACT

The response of glasses to mechanical loading often leads to the formation of inhomogeneous flow patterns that may strongly affect the materials properties. Among them, shear bands, associated with strain localization in form of band-like structures, are ubiquitous in a wide variety of materials, ranging from soft matter systems to metallic alloys. Molecular dynamics simulations of the Kob-Andersen Lennard-Jones mixture are performed to investigate the onset of flow and the subsequent formation of shear bands. Deeply supercooled systems as well as systems far below the glass transition temperature are sheared, using a planar Couette flow geometry. Shear is imposed via the boundaries, using Lees-Edwards boundary conditions at a constant strain rate. We show that the onset of flow is marked by a directed percolation transition of mobile regions [1]. Shear banding is observed at sufficiently low strain rates. We analyze the nucleation of the shear-banded structures as well as the mechanical properties of the deformed glasses. [1] G. P. Shrivastav, P. Chaudhuri, and J. Horbach, Yielding of glass under shear: a directed percolation transition precedes shear-band formation, Phys. Rev. E 94, 042605 (2016).

Integrated Earthquake Simulation for Estimation of Earthquake and Tsunami Hazard and Disaster Using HPC

Muneo Hori*, Takamasa Iryo**, Takane Hori***

*The University of Tokyo, **Kobe University, ***JAMSTEC

ABSTRACT

Integrated earthquake simulation (IES) is aimed at computing whole processes of earthquake hazard and disaster, The core idea of IES is seamlessly combining various numerical analysis methods such as earthquake generation analysis, structural seismic response analysis and social disaster recovery analysis. IES has implemented a few analysis methods in it which use HPC so that a larger urban area is computed considering various earthquake scenario. A smart platform that automatically construct suitable analysis models for implemented analysis methods is developed. This platform uses various data resources such as 3D maps and local government inventory. In this presentation, the current state of developing IES is explained, and a few examples of integrated simulations of earthquake hazard and disaster estimation in actual cities in Japan are presented.

A Proposal of Monitoring and Forecasting Method for Crustal Activity in and Around Japan with 3D Heterogeneous Medium Using a Large-Scale High-Fidelity Finite Element Simulation

Takane Hori*, Tsuyoshi Ichimura**, Kohei Fujita***, Ryoichiro Agata****, Takuma Yamaguchi*****

*Japan Agency for Marine-Earth Science and Technology, **Earthquake Research Institute, The University of Tokyo, ***Earthquake Research Institute, The University of Tokyo, ****Japan Agency for Marine-Earth Science and Technology, *****Earthquake Research Institute, The University of Tokyo

ABSTRACT

Recently, we can obtain continuous dense surface deformation data on land and partly on the sea floor. The obtained data are not fully utilized for monitoring and forecasting of crustal activity, such as spatio-temporal variation in slip velocity on the plate interface including earthquakes, seismic wave propagation, and crustal deformation. For construct a system for monitoring and forecasting, it is necessary to develop a physics-based data analysis system including (1) a structural model with the 3D geometry of the plate interface and the material property such as elasticity and viscosity, (2) calculation code for crustal deformation and seismic wave propagation using (1), (3) inverse analysis or data assimilation code both for structure and fault slip using (1) & (2). To accomplish this, it is at least necessary to develop highly reliable large-scale simulation code to calculate crustal deformation and seismic wave propagation for 3D heterogeneous structure. Unstructured FE non-linear seismic wave simulation code has been developed. This achieved physics-based urban earthquake simulation enhanced by 1.08 T DOF x 6.6 K time-step. A high fidelity FEM simulation code with mesh generator has also been developed to calculate crustal deformation in and around Japan with complicated surface topography and subducting plate geometry for 1km mesh. This code has been improved the code for crustal deformation and achieved 2.05 T-DOF with 45m resolution on the plate interface. This high-resolution analysis enables computation of change of stress acting on the plate interface. Further, for inverse analyses, waveform inversion code for modeling 3D crustal structure has been developed, and the high-fidelity FEM code has been improved to apply an adjoint method for estimating fault slip and asthenosphere viscosity. Hence, we have large-scale simulation and analysis tools for monitoring. We are developing the methods for forecasting the slip velocity variation on the plate interface. Although the prototype is for elastic half space model, we are applying it for 3D heterogeneous structure with the high-fidelity FE model. Furthermore, large-scale simulation codes for monitoring are being implemented on the GPU clusters and analysis tools are developing to include other functions such as examination in model errors.

A Simple Direct-Forcing Immersed Boundary Projection Method with Prediction-Correction for Fluid-Solid Interaction Problems

Tzyy-Leng Horng*, Po-Wen Hsieh**, Suh-Yuh Yang***, Cheng-Shu You****

*Feng Chia University, **National Chung Hsing University, ***National Central University, ****National Central University

ABSTRACT

In this paper, we propose a simple and novel direct-forcing immersed boundary (IB) projection method in conjunction with a prediction-correction (PC) process for simulating the dynamics of fluid-solid interaction problems, in which each immersed solid object can be stationary or moving in the fluid with a prescribed velocity. The method is mainly based on the introduction of a virtual force which is distributed only on the immersed solid bodies and appended to the fluid momentum equations to accommodate the inter- nal boundary conditions at the immersed solid boundaries. More specifically, we first predict the virtual force on the immersed solid domain by using the difference between the prescribed solid velocity and the computed velocity, which is obtained by applying the Choi-Moin projection scheme to the incompressible Navier-Stokes equations on the entire domain including the portion occupied by the solid bodies. The pre- dicted virtual force is then added to the fluid momentum equations as an additional forcing term and we employ the same projection scheme again to correct the velocity field, pressure and virtual force. Although this method is a two-stage approach, the computational cost of the correction stage is rather cheap, since the associated discrete linear systems need to be solved in the correction stage are same with that in the prediction stage, except the right-hand side data terms. Such a PC procedure can be iterated to form a more general method, if necessary. The current two-stage direct-forcing IB projection method has the advantage over traditional one-stage direct-forcing IB projection methods, consisting of the prediction step only, by allowing much larger time step, since traditional methods generally request quite small time step for flow field relaxed and adjusted to the solid body movement even using implicit scheme. Numerical experiments of several benchmark problems are performed to illustrate the simplicity and efficient performance of the newly proposed method. Convergence tests show that the accuracy of the velocity field is super-linear in space in all the 1-norm, 2-norm, and maximum norm. We also find that our numerical results are in very good agreement with the previous works in the literature and one correction at each time step appears to be good enough for the proposed PC procedure. Keywords: incompressible Navier-Stokes equations, fluid-solid interaction, immersed boundary method, projection scheme, direct-forcing method, prediction-correction

Pointwise Divergence-free Higher Order Space-time Hybridizable and Embedded Discontinuous Galerkin Methods for Incompressible Flows

Tamas Horvath*, Sander Rhebergen**

*University of Waterloo, **University of Waterloo

ABSTRACT

The Space-time Discontinuous Galerkin (ST-DG) method is an excellent method to discretize problems on deforming domains. This method uses DG to discretize both in the spatial and temporal directions, allowing for an arbitrarily high order approximation in space and time. Furthermore, this method automatically satisfies the geometric conservation law which is essential for accurate solutions on time dependent domains. We present a higher-order accurate Hybridizable or Embedded Discontinuous Galerkin (DG-H or DG-E) method for incompressible flows. This discretization guarantees a pointwise divergence-free velocity field on simplicial meshes.

Topology Optimization for Elastoplastic Large Deformation Considering Various Hardening Behavior with Multiplicative Decomposition

Hiroya Hoshiba*, Junji Kato**, Takashi Kyoya***

*Tohoku University, **Tohoku University, ***Tohoku University

ABSTRACT

The present study proposes an advanced topology optimization method for elastoplastic large deformation. This method includes description of finite strain kinematic hardening and can be applied exactly to optimal design of structures subjected to historical loading. Regarding topology optimization considering finite elastoplasticity, a previous work by [1] introduces sensitivity analysis based on the so-called transient adjoint method. However, kinematic hardening behavior in addition to finite strain theory has yet to be considered. On the other hand, a conditional sensitivity analysis for elastoplastic composites has been proposed by [2] and low-cost and accurate sensitivity analysis is achieved. In this study, we extend the conditional approach and incorporate the advanced elastoplastic material model into the conventional topology optimization framework. In formulating finite strain elastoplastic model including kinematic hardening law, all deformations are decomposed in a multiplying manner according to their meanings. Hence elastoplastic constitutive equations are described with reference to two different plastic intermediate configurations. Based on this special property, new sensitivity analysis is precisely formulated and sensitivity is analytically derived to carry out gradient-based optimization algorithm. Finally, several numerical examples will be shown to discuss practical concerns, e.g. accuracy in sensitivity, computational costs and its numerical convergence. REFERENCES: [1] M. Wallin, V. On Thermo-electro-mechanics of Electro-active Polymers

Mokarram Hossain*

*Zienkiewicz Centre for Computational Engineering, Swansea University, UK

ABSTRACT

Electro-active polymers (EAPs) draw considerable attention thanks to large actuation mechanisms. EAPs are nowadays well-known and promising candidates for producing sensors, actuators and energy harvesters. In general, polymeric materials are sensitive to differential temperature histories. Moreover, it is a non-trivial task to maintain a prescribed temperature during experimental characterizations of EAPs under electro-mechanically coupled loads. Such difficulties to maintain constant temperature is not only because of an external differential temperature history but also because of the changes in internal temperature caused by the application of high electric loads. In this contribution, a thermo-electro-mechanically coupled constitutive framework is proposed based on the total energy approach. Departing from relevant laws of thermodynamics, thermodynamically consistent constitutive equations are formulated. To demonstrate the performance of the proposed thermo-electro-mechanically coupled framework, several non-homogeneous boundary-value problems will be solved. The results illustrate the influence of various thermo-electro-mechanical couplings [1, 2, 3]. 1. M. Mehnert, M. Hossain, P. Steinmann, On nonlinear thermo-electro-elasticity, Proc. R. Soc. CAD-integrated Template-based Patient-Specific Vascular Modeling for Isogeometric Analysis

Shaolie Hossain*, Benjamin Urick**, Travis Sanders***, Jessica Zhang****, Thomas Hughes*****

*The University of Texas at Austin, **The University of Texas at Austin, ***The University of Texas at Austin, ****Carnegie Mellon University, *****The University of Texas at Austin

ABSTRACT

Patient-specific vascular modeling typically involves three fundamental steps: image processing, analysis suitable model generation, and computational analysis. Analysis suitable model generation techniques that are currently utilized suffer from several difficulties and complications, which often necessitate manual intervention and crude approximations. Because the modeling pipeline spans multiple disciplines, the benefits of integrating a computer-aided design (CAD) component that offers a robust, intuitive, and highly customizable framework for the geometric modeling tasks has been largely overlooked. In this work, we present a CAD-integrated template-based modeling framework that streamlines the construction of solid NURBS (non-uniform rational B-spline) vascular models for performing isogeometric finite element analysis. Examples of arterial models for mouse and human circles of Willis and a porcine coronary tree are presented. The benefits of the presented approach, such as quicker processing time and more accurate reconstruction of complex models, are also highlighted.

Mixed-mode Fracture Analysis in Brittle and Quasi-brittle Materials Based on the Generalized Maximum Energy Release Rate Criterion

Cheng Hou*, Xueling Fan**

*Xi'an Jiaotong University, **Xi'an Jiaotong University

ABSTRACT

In this paper, a modified mixed-mode fracture model called generalized maximum energy release rate criterion is proposed, which simultaneously involves the effects of the mixed-mode I/II stress intensity factors and the T-stress. This model can be used to predict the mixed-mode I/II crack initiation angles and fracture resistances in brittle and quasi-brittle materials. The results show that the T-stress plays an important role on the mixed-mode fracture analysis when an energy-based criterion is employed. Moreover, a series of mixed-mode fracture prediction curves are compared with the experimental results in literatures for semi-circular bend specimens made of PMMA and central cracked Brazilian disk specimens of Neiriz marble. Comparison results show that the modified criterion proposed in this work performs better in predicting the crack initiation angles and the fracture resistances than the conventional maximum energy release rate criterion. Key words: maximum energy release rate criterion; mixed mode; T-stress; crack initiation angle; fracture resistance

Dynamic Meshing Analysis of Spur Gear Based on the Modified Vector Form Intrinsic Finite Element (VFIFE) Method

Xiangying Hou*, Zongde Fang**, Jinke Jiang***

*Northwestern Polytechnical University, **Northwestern Polytechnical University, ***Chang'an University

ABSTRACT

Lumped-mass method and dynamic equations are the most commonly used methods in the dynamic analysis due to its less computation amount than finite element method. However, the lumped-mass method has its own problems: limited accuracy, strong subjectivity and unable to display stress and displacement distribution. To solve dynamic non-linear problems, we proposed the modified vector form intrinsic finite element (VFIFE) method, which reduce computational complexity compared to the traditional VFIFE method [1]. Even though explicit difference is adopted, the advantages of good convergence and simple algorithm make it suitable for high-speed problems. In this paper, we combined contact algorithm and the modified VFIFE method to simulate spur gear dynamics and also rewrote the central difference equation considering Rayleigh damping. Taking a specific gear pair for example, we could obtain the transmission error response as well as the stress distribution, contact pattern and contact force to guide design. We could obtain rather precise results with a coarse mesh and the numerical results show the effectiveness and accuracy of the proposed method [2-4]. In addition, this method is not limited to gear analysis, but suitable for high-speed non-linear problems in engineering fields. [1] X. Hou, Z. Simulations of Suspension Flows with a Meshless Moving Least Squares Scheme

Amanda Howard*, Martin Maxey**

*Brown University, **Brown University

ABSTRACT

This talk will focus on a meshfree method for simulations of neutrally buoyant, non-Brownian particles in Stokes flow. We will discuss a meshless scheme using Moving Least Squares polynomial reconstructions to provide a computationally efficient method with higher order accuracy for use with general boundary conditions and arbitrary polynomial shapes while maintaining stability. In finite difference schemes for Stokes flow, satisfying an inf-sup condition is necessary to control spurious pressure modes. Without a mesh, this framework is not applicable. Here, a finite difference-like staggered discretization is used to couple a divergence-free velocity and pressure reconstruction, resulting in a stable meshless scheme for Stokes flow that can be coupled with the motion of particles suspended in the flow [1]. The emphasis will be on applications to dense suspensions of particles, especially particles with polydispersed sizes and non-spherical shapes. The presentation here will discuss the implementation in 3D with multiple particles and how the results can be used to benchmark other lower fidelity methods such as the Force Coupling Method. In meshless methods, the boundaries of the particles are sharply defined, allowing for sharp resolution for problems such as heat conduction. Variably Thermalized Soft Glassy Rheology

Robert Hoy*

*Physics, University of South Florida

ABSTRACT

We present a version of soft glassy rheology that includes thermalized strain degrees of freedom. It fully specifies systems' strain-history-dependent positions on their energy landscapes and therefore allows for quantitative analysis of their heterogeneous yielding dynamics and nonequilibrium deformation thermodynamics. We first illustrate the very different characteristics of thermal and athermal plasticity by contrasting systems' evolution under thermalized vs. nonthermalized plastic flow rules. Then we present a generalized flow rule that continuously interpolates between thermalized and nonthermalized flow, and use it to analyze more realistic scenarios wherein flow is partially thermalized.

Fluid-Structure Interaction Analysis of Transcatheter Heart Valves

Ming-Chen Hsu*, Michael C.H. Wu**

*Iowa State University, **Iowa State University

ABSTRACT

Transcatheter heart valves (THVs) have emerged as a minimally invasive alternative to surgical bioprosthetic heart valves therapy. THVs offer advantages such as less postoperative pain, faster rehabilitation, and better pressure gradients. However, issues such as paravalvular leakage, leaflet fatigue, and valve migration limit the widespread use of THV in the younger population, especially due to the lack of data concerning its long-term performance and durability. In this work, we develop and apply a biomechanically rigorous and physiologically realistic computational fluid-structure interaction framework based on immersogeometric analysis to study the combined effect of leaflet geometry, biomaterial property, and blood flow pattern on valve performance.

ABSTRACT

Among the whole population, small, obese, and/or older occupants are at increased risk of death and serious injury in motor-vehicle crashes compared with mid-size young men. Current adult finite element (FE) human body models (HBM) have been developed in a few body sizes (large male, midsize male, and small female) with reference body dimensions similar to those of the available physical anthropomorphic test devices (ATDs). The limited number of body sizes available has resulted in part because the time needed to develop an FE HBM using typical methods is measured in months or even years. In this study, we developed an automated component-based mesh morphing method that can sequentially morph the component geometries of the Global Human Body Model Consortium (GHBMC) mid-size male model into target geometries for a diverse population predicted by a set of statistical geometry models for ribcage, pelvis, femur, tibia, and external body surface. We also included a system to automatically correct/smooth highly distorted mesh in the models. Using the new method, twelve models were developed representing seated occupants with a wide range of stature (175 cm and 188 cm), body-mass index (BMI) (25, 30 and 35) and age (30 and 70 years old). The newly generated human body models showed similar mesh quality compared to the original GHBMC model and. They also displayed no significant changes in BMI from target values. The component-based mesh morphing method was also found to be relatively faster and more efficient than the previous region-based mesh morphing method due to landmark reduction in each morphing step. The morphed models were subjected to six regional impact simulations, including abdominal bar impact, oblique abdominal hub impact, frontal thorax hub impact, lateral shoulder impact, impact to the pelvis, and lateral thorax impacts. The simulation boundary conditions were set based on those reported in the PMHS tests. The simulation results were then compared to the PMHS test corridors. Overall, the simulation results displayed large variations among the 12 morphed models and strong correlations between human characteristics and human impact responses. However, age, height, and BMI showed different trends depending on the type of impact, which were generally consistent with the literature. This study demonstrated the robustness of the component-based mesh morphing method to generate reliable human models for a diverse population and effectively use these models for impact simulations. ? A Progressive Bearing Damage and Failure Model for Composite Interference-fit Joints

Junshan Hu*, Hailin Li**, Kaifu Zhang***

*Northwestern Polytechnical University, **Northwestern Polytechnical University, ***Northwestern Polytechnical University

ABSTRACT

The interference-fit joint is widely used for thin-walled composite sheets assembly in aviation field. Understanding the damage and failure mechanism of such joint structures has great importance for optimal design of composite joining. Therefore, an evaluation method for the initial and progressive failure of composite interference-fit joints was proposed based on the Hashin type criteria and damage mechanics. In the model, the initial failure (crack initiation in the fiber and/or matrix) and progressive failure (crack growth in the fiber and/or matrix) were evaluated using the separate fiber- and matrix-dependent damage variables, respectively. The user-defined subroutine UMAT was developed based on coupling theories of the failure criterion and damage mechanics in order to efficiently analyze the progressive failure phenomenon in the bearing region of the composite joints. In addition, a technique based on viscous regularization, a characteristic element length and fracture energies of fiber and matrix are used in the model to alleviate mesh-dependence and improve convergence. The influence of interference-fit size, clamping force and applied external loading on damage evolution and failure are considered and good agreements are observed in experimental results.

Skew-symmetric Nitsche's Formulation and Applications in Isogeometric Analysis

Qingyuan Hu*, Franz Chouly**, Stéphane Bordas***, Ping Hu****, Gengdong Cheng*****

*Dalian University of Technology, **Université Bourgogne Franche-Comté, ***University of Luxembourg, ****Dalian University of Technology, *****Dalian University of Technology

ABSTRACT

An universal and simple skew-symmetric Nitsche's formulation is introduced into isogeometric analysis (IGA). The derivation of the skew-symmetric Nitsche's formulation is straightforward if one starts from the standard symmetric Nitsche's formulation, and the obtained Nitsche terms are skew-symmetric. Variants of presented formulation are suitable for essential applications in IGA: (displacement or rotational) boundary conditions imposing, patch coupling, and moreover contact problems for the first time in IGA to our knowledge. For boundary conditions imposing, an important advantage of the skew-symmetric Nitsche's formulation is that there is no need to deal with the stabilization parameter as in the standard symmetric Nitsche's formulation. Numerical tests showed that the Nitsche's formulation could impose boundary conditions successfully in a weak sense. For patch coupling, the skew-symmetric Nitsche's formulation is also parameter-free. Through numerical studies it is observed that the condition number of the stiffness matrix by the skew-symmetric Nitsche's formulation is much smaller than the standard symmetric one. In cases of free vibration, the coupling process introduces “outlier” frequencies and corresponding eigenmodes, which are highly localized at these coupled interfaces. The Nitsche's contact formulation is able to theoretically recover the contact (KKT) conditions, it depends mush less on the stabilization parameter than the penalty method, and does not introduce extra degrees of freedom as the Lagrange multiplier method. Numerical tests illustrated that the skew-symmetric Nitsche contact formulation can predict the contact pressure distribution to some extent, in addition it behaves more robustly with respect to the stabilization parameter, the element length ratio on contact boundary, and the order of adopted shape functions than the standard one.

Smoothed Particle Galerkin Method with a Second-order Accurate Momentum-Consistent Algorithm for Simulating Thermal-Mechanical Flow Drill Screw Processes

Wei Hu*, C.T. Wu**, Xiaofei Pan***

*Livermore Software Technology Corporation, **Livermore Software Technology Corporation, ***Livermore Software Technology Corporation

ABSTRACT

In this paper, we present a stabilized Galerkin approximation in a meshfree framework [1] for the simulation of metal threading in the three-dimensional Flow Drill Screw (FDS) process. A second-order accurate momentum-consistent smoothing algorithm is proposed for the desired stability and accuracy in the meshfree structural analysis using the particle integration. A staggered explicit time integration scheme is employed to couple thermal and mechanical systems of equations. To avoid the tension instability in the nonlinear structural analysis, an adaptive anisotropic Lagrangian kernel [2] is considered in the formulation which makes it possible to handle the severe deformation problem in simulating the thread forming phenomena. A bond-based material failure criterion [3] is adopted to prevent the excessive straining due to the assumption of continuous approximation of displacement field in meshfree Galerkin approach. Finally, a three-dimensional FDS problem is analyzed to demonstrate the effectiveness of the present meshfree numerical procedure. [1] C.T. Wu, M. Koishi, W. A Symplectic Analytical Singular Element for Thermal Conduction with Singularities in Anisotropic Material

Xiaofei Hu*, Weian yao**

*Dalian University of Technology, **Dalian University of Technology

ABSTRACT

Thermal conduction problem with singularity in anisotropic materials is still challenging. This is mainly because the thermal conductivity coefficients become functions of the angular coordinate under the polar coordinate system. The analytical study become extremely complex especially when multiple bounded materials are involved in the problem. In order to solve this problem, a sub-field method is first introduced to divide the material around crack tip into several fields in which the material properties are assumed constants under the polar coordinate system. For each sub-field, the symplectic dual approach is then applied to find the general solution of eigen solution. The relationship among the eigen solution of the sub-fields are constructed through the compatibility conditions at the interface between adjacent sub-fields. Then, a symplectic analytical singular element (SASE) is constructed of which the displacement and stress fields are defined by the obtained eigen solutions. The SASE contains rich information of the analytical eigen solution of the boundary value problem and hence is very accurate and efficient for the discussed problem. The general intensity factors can be solved directly without any post-processing. A few numerical examples are worked out to demonstrate the proposed method.

Atomistic Dislocation Core Energies and the Calibration of Discrete Dislocation Dynamics

Yi Hu*, W. A. Curtin**

*LAMMM, EPFL, **LAMMM, EPFL

ABSTRACT

The method of Discrete Dislocation Dynamics (DDD) [1] has emerged as a valuable tool for modeling the collective behavior of dislocations at the mesoscale, providing insights into a range of plasticity phenomena. DDD uses a continuum line description of the dislocation, with various phenomena controlled by atomistic aspects, such as the Peierls stress, mobility, and core energy, introduced as parameters. To achieve quantitative predictive capability, reflecting real materials, the DDD method can benefit from various improvements, such as anisotropic elasticity [2], partial dislocations for fcc and hcp crystals, and accurate core or self energies. Some phenomena require atomistic resolution, and hence the calibration of DDD to specific atomistic behavior is valuable. Here, we use molecular statics simulations to accurately determine the total dislocation energy in fcc crystals, from which we derive core energies necessary to represent the total energy within anisotropic elasticity. The variation in core energy versus dislocation character deviates significantly from the results obtained by continuum linear elastic dislocation theory. We then examine the use of the derived core energy in a established DDD methods for predicting dislocation line tension in a simple bow-out problem. We are unable to reach agreement between such DDD simulations and fully atomistic simulations of the bow-out process in fcc Al [3]. Since fcc dislocations dissociate into two partial dislocations separated by a stacking fault, the analysis is extended to extract the core energies of partial dislocations as a function of dislocation character. Results are also compared to other recent studies of atomistic core energies. The prospects for quantitative linking of atomistic and DDD descriptions of dislocations are discussed in light of our findings. [1] A. Arsenlis, W. Cai, M. Tang, M. Rhee, T. Oppelstrup, G. ABSTRACT

Metallic glasses (MGs) have exhibited many promising properties such as high yield strength, low friction coefficient and high resistance to corrosion, oxidation and wear. However, the localized deformation and poor ductility due to shear bands prohibit the further applications of MGs. In this study, a mesoscale model combining the kinetic Monte Carlo algorithm and the finite element method is developed to investigate the deformation behaviors of MGs. The shear transformation zone (STZ) is viewed as the fundamental deformation unit and each nanoscale volume element in the MGs is considered as a potential STZ. The mesoscale modeling is capable of simulating MGs processing and deformation on time and length scales greater than those by atomistic modeling. The proposed computational framework is firstly verified by a sanity check and then applied to simulate uniaxial tension test. Simulations of the uniaxial tension demonstrate the key factor of the shear band formation is the strain-induced softening.

A Non-ordinary State-based Peridynamic Modeling for Hydraulic Fracture

Dan Huang*, Yubin Zhang**, Yepeng Xu***

*Hohai University, **Hohai University, ***Hohai University

ABSTRACT

A coupled fluid-structure interaction model based on the peridynamic theory has been proposed and applied to hydraulic fracture problems. A nonlocal constitutive model which can describe the mechanical behavior and fracture characteristics of rock and concrete-like quasi-brittle materials is proposed based on the non-ordinary state-based peridynamic theory. An equivalent hydraulic pressure term coupled with flow equation was embedded in the peridynamic model to describe the fluid flow and track the hydraulic pressure on the new-born crack surfaces. Considering the contact between surfaces of cracks, a short-range repulsive force between material points was implemented and corresponding contact algorithms were developed. The proposed model and algorithms were validated through simulating the hydraulic fracture of typical concrete gravity dams in different loading cases, and comparing the numerical results with experimental observations and other numerical results. Key words?hydraulic fracture; crack propagation; state-based peridynamics; contact *Acknowledgement: The support of the National Natural Science Foundation of China (No. 51679077) and the Fundamental Research Funds for the Central Universities in China (Nos. 2015B18314, 2017B13014) is gratefully acknowledged. A Family of Non-Oscillatory Embedded Boundary Methods for Viscous Flow and Fluid-Structure Interaction Problems

Daniel Huang*, Charbel Farhat**

*Stanford, **Stanford

ABSTRACT

The second-order Finite Volume method with Exact two-material Riemann Problems (FIVER) [1] is both a computational framework for multi-material flows characterized by large density jumps, and an Embedded Boundary Method (EBM) for CFD and highly nonlinear Fluid-Structure Interaction (FSI) problems [2]. For FSI problems, this EBM has demonstrated the ability to address viscous effects along wall boundaries [3], and large deformations and topological changes of such boundaries [2]. However, like for most EBMs, its performance in the vicinity of a wall boundary can be sensitive with respect to the position and orientation of this boundary relative to the embedding mesh. This is due to ill-conditioning issues that arise when an embedded discrete surface becomes too close to a node of the embedding mesh, which may lead to spurious oscillations in the computed solution gradients at the wall boundary. These issues are resolved here by introducing an alternative definition of the active/inactive status of a mesh node that removes all sources of ill-conditioning. Two additional contributions are presented. The first one is a new procedure for constructing the fluid-structure half Riemann problem underlying the semi-discretization by FIVER of the convective fluxes that replaces one extrapolation by an interpolation. The second contribution is a post-processing algorithm for computing quantities of interest at the wall that achieves smoothness in the computed solution and its gradients. Lessons learned from these enhancements are then generalized to eliminate from the original version of FIVER its aforementioned sensitivities while maintaining the original definition of the status of a mesh node. This leads to a family of second-generation, second-order FIVER methods whose performance is illustrated in this talk for a challenging flow problem over a bird wing characterized by a feather-induced surface roughness, and a complex flexible flapping wing problem for which experimental data is available. 1. High Performance Computing of Distortion and Stresses in Welded and Additive Manufactured Structures

Hui Huang*, Chen Jian**, Zhili Feng***

*Oak Ridge National Laboratory, **Oak Ridge National Laboratory, ***Oak Ridge National Laboratory

ABSTRACT

Numerical simulation is an efficient way to better understand the thermal and mechanical evolution during welding and additive manufacturing (AM) processes and to design and optimize the processes. However, with today's computational tools, thermal-mechanical simulation of the continuous metal depositing process is extremely time-consuming. As a result, many simulation models proposed so far are based on simplification that either the continuous manufacturing pass is lumped, or the dimension of model is decreased. For example, residual stress simulation of multipass girth welds are mostly performed using two-dimensional (2D) axisymmetric models. In this study, a new finite element code recently developed in house at Oak Ridge National Lab was used for simulation of both welding and additive manufacturing. Our new code effectively utilizes GPU based high-performance computers to allow for realistic simulation of the transient thermal and mechanical response of materials during arc based manufacturing process. Our code further accelerates based on the consideration of unique physics associated with manufacturing processes that are characterized by steep temperature gradient and a moving heat source. It is capable of modeling large-scale problems that cannot be easily handled by the existing commercial simulation tools. To demonstrate the accuracy and efficiency, our in-house code was compared with the commercial modeling tools by simulating a single pass pipe girth weld. Our code achieved comparable solution accuracy with respect to the commercial one but with over 100 times less on computational cost. Moreover, a multi-pass girth weld model with over 1 million elements and 180 thousand time-steps was successfully analyzed in 3.2 days. The 3D analysis demonstrated more realistic stress distribution that is not necessarily axisymmetric along the hoop direction. A benchmark study on a cylinder model by selective laser melting was also carried out and compared to the experimental measurements. Distortion shape was well reproduced by the new code and computational time was drastically reduced relative to that by commercial model. Effects of layer-by-layer activation and element-by-element activation scheme on distortion and stress accuracy was clarified by the efficient numerical model.

Non-reciprocal Wave Propagation in Time-varying Modulated Lattices

Jiahui Huang*, Yuchen Zhao**, Xiaoming Zhou***

*Key Laboratory of Dynamics and Control of Flight Vehicle, Ministry of Education and School of Aerospace Engineering, Beijing Institute of Technology, Beijing 100081, China, **Key Laboratory of Dynamics and Control of Flight Vehicle, Ministry of Education and School of Aerospace Engineering, Beijing Institute of Technology, Beijing 100081, China, ***Key Laboratory of Dynamics and Control of Flight Vehicle, Ministry of Education and School of Aerospace Engineering, Beijing Institute of Technology, Beijing 100081, China

ABSTRACT

The modulated mediums are materials whose properties could vary periodically in both the space and time. Non-reciprocal wave propagation can be acquired in the modulated medium, and is expected to bring new technological concepts to wave-control engineering. In this work, we study an infinite space-time lattice structure composed of the time-varying mass and the spring of constant stiffness. The Bloch-based theoretical method is developed for the computation of the dispersion diagrams of the modulated lattice system. It is found that the asymmetric band of the fundamental branch emerges if the spatiotemporal modulation of inertial mass constitutes a travelling-wave field pattern, which behaves like a biasing field that breaks the time-reversal symmetry. Asymmetric bandgaps are opened due to the modulation-induced mode interaction of different orders. A purely unidirectional bandgap can be available when the super cell involves over three time-varying elements, and the phase difference of time-varying mass between adjacent elements is the same. The effect of modulating frequency and amplitude of time-varying mass is analyzed. It is found that the modulating frequency affects primarily the frequency position of the asymmetric bandgap, while the modulating amplitude determines its frequency bandwidth. We also study the non-reciprocal wave phenomenon in modulated lattices involving simultaneous time-driven mass and stiffness. Adding the space-time modulation over stiffness leads to the wider asymmetric bandgap and the flexible control on the gap position. Finally, we will present some possible designs of structured elements with time-varying mass and/or time-varying stiffness. The modulated lattice structure is expected to open a new avenue in the unprecedented control over sounds and vibrations. Reference: Trainiti, G., Ruzzene, M., 2016. On the Accurate and Efficient Simulation of Ferrofluids

Libo Huang*

*KAUST

ABSTRACT

Ferrofluid, due to its peculiar behavior in the magnetic field, has drawn the attention from various disciplines. In contrast to its wide applications, its large-scale simulation is less addressed. Previous simulations are mesh-based, while we present a method tackling the problem on a particle basis. The core idea is to treat each particle as a distribution (e.g. symmetric truncated Gaussian) of fluid. The aggregation of all particles forms the spatial distribution of the ferrofluid. In the external field, the ferrofluid acts as a soft magnetizable material, and the total magnetic field is the sum of the external field and the field generated by the ferrofluid itself, called the demagnetization field. The magnetization relationship is nonlinear, but the total demagnetization field is a linear combination of the field generated by each particle (distribution). Since each particle after magnetization would affect other particles, an optimization method is used to get the final magnetic field, minimizing the difference between the demagnetization field influencing the particles, and the demagnetization field generated by the particles. With the final magnetic field, various force models can be used, either classical Kelvin forces or modern forces derived from thermodynamics. Combining the force term and surface tension with existing Navier-Stokes solvers, either pure Lagrangian, for example, the Smooth Particle Hydrodynamics (SPH) method, or mixed Eulerian and Lagrangian for example the (Afine) Particle In Cell ((A)PIC) method, one can obtain both accurate and efficient large-scale simulations of ferrofluids.

ABSTRACT

CO2 geosequestration into deep saline aquifers may be a viable strategy for reducing greenhouse gas emissions and mitigating anthropogenic climate change. In CO2 geosequestration, the CO2 is commonly compressed into supercritical CO2 and injected into the aquifers for long-term storage. The structural and residual trapping capacities of the aquifers depend on CO2-brine interfacial tension and contact angle in CO2-brine-mineral geophysical systems. While earlier molecular dynamics (MD) simulations have been used to study the CO2-brine interfacial tension and the static contact angles of CO2-brine-mineral systems at different temperatures and pressures, we study in this work the dynamic contact angles of CO2-water-silica systems during supercritical CO2 injections at different injection rates with MD. The supercritical CO2 flow induced by a moving piston is injected into water between two parallel silica plates; the simple point charge (SPC) water model (Teleman, Jönsson, & Engström, 1987), the elementary physical model (EPM2) for CO2 molecules (Nieto-Draghi, de Bruin, Pérez-Pellitero, Bonet Avalos, & Mackie, 2007) and the silica surface model developed by (Emami et al., 2014) are used in these simulations. Both intramolecular and intermolecular degrees of freedom are considered in the simulations. The interaction parameters between dissimilar atoms are computed using Lorentz-Berthelot combining rules. Scenarios with different area densities of the silanol groups on the silica surfaces are also considered to reproduce hydrophilic and hydrophobic surfaces. The preliminary results show the dependence of dynamic contact angles on injection rates. This study will help us better understand and predict the mechanism of CO2 injections and the storage capacities in deep saline aquifers. References Emami, F. S., Puddu, V., Berry, R. Interface Structure Dependent Incipient Plasticity of Graphene/Cu Nanomultilayers

Ping Huang*, Shuang Zhang**, Fei Wang***

*State Key Laboratory for Mechanical Behavior of Material,School of Materials Science and Engineering, Xi'an Jiaotong University, **State Key Laboratory for Mechanical Behavior of Material,School of Materials Science and Engineering, Xi'an Jiaotong University, ***State Key Laboratory for Strength and Vibration of Mechanical Structures, School of Aerospace, Xi'an Jiaotong University

ABSTRACT

Even though graphene possesses extremely high strength and elastic modulus, it is still a challenge to use it as structural materials due to its extrinsic dimension limit. Then, composite structure combined graphene and proper metals, i.e., graphene/metal nanocomposites, was proposed to be a possible way recently to achieve diverse properties that cannot provided by single constituent material. For nanocomposites, interface structure generally played a significant role in determining mechanical properties as individual layer thickness of the constituent layers decreases to less than tens of nanometers, such as interface structure transition, acting as sources for nucleating dislocations. Unlike the well documented metal/metal composites, the mechanisms and how interface structure evolve upon plastic deformation in the graphene/metal composites are still unclear and under intense debate. In the present study, molecular dynamics simulations were used to explore the interface structure and the inception of plasticity of graphene/Cu nano-multilayers. Specific attention was paid on how the graphene/Cu interface structural features affect the strength of the nano-multilayers. After relaxation, the strain distribution along graphene/Cu interface was non-uniform. The role of the interface structure in the plastic deformation of graphene/Cu nano-multilayers was studied under two loading axis, and it was found (i) preferential slip systems within Cu layers all followed the Schmid factors and regular nucleation sites were from interface where the local strain is the highest, which behavior is different from other metal/metal system, and (ii) dislocations propagated in two {111} slip planes with the partial dislocation 1/6<1 1 2> along the specific directions in which the strain is higher. In addition, incipient plastic deformation originated from the graphene/Cu interface could effectively enhances the strength and elastic modulus of the graphene/Cu nano-multilayers compared with nanocrystalline Cu. It was concluded the interface strain changes the nucleating behavior and graphene acting as a constrained layer leads to the strengthening effect.

A Fractional Viscoelastic Model for Shape Memory Polymers

Rong Huang*, Zhouzhou Pan**, Zishun Liu***

*International Center for Applied Mechanics, State Key Laboratory for Strength and Vibration of Mechanical Structures, Xi'an Jiaotong University, **International Center for Applied Mechanics, State Key Laboratory for Strength and Vibration of Mechanical Structures, Xi'an Jiaotong University, ***International Center for Applied Mechanics, State Key Laboratory for Strength and Vibration of Mechanical Structures, Xi'an Jiaotong University

ABSTRACT

Shape memory polymers (SMPs) have been widely studied because they can recover from a deformed shape to their original shape by a certain external stimulus. In order to investigate this interesting process and predict this kind of deformation behavior, many researchers have generated constitutive models from different aspects of views. However, most of the proposed constitutive models include a great amount of parameters and these parameters must be carefully selected and verified by a large amount of experiments. This complex process not only generate extra work for data processing but also limits the application and development of the constitutive models. Therefore, it is indispensable to develop a new constitutive model which can take into account both the accuracy and the simplicity. From the experiment observations, we found that the majority of shape memory polymers show a power-law type relaxation behavior instead of an exponential type correlations curve between relaxation modulus and time. Considering this phenomenon, we propose a fractional viscoelastic constitutive model with less parameters for SMP which give good agreement with the experimental thermomechanical behavior of SMPs and also reduces the workload of parameters fitting. The article draw up to match through frequency and time sweep curve fitting form previous SMP experiments to establish the mathematics model. Then we applied the model to calculate the SMP behavior during uniaxial tension and free recovery process under different loading cases. Both the mathematical model and the real experiment results give good consistency. In addition, the comparison between an integral and fractional viscoelastic models of SMP are discussed in our study. We hope the proposed model in our researches could provide some new ideas in designing and optimizing potential SMP applications.

Steady-State Crack Growth in Polymer Gels by Linear and Nonlinear Poroelastic Models

Rui Huang*, Yalin Yu**, Chad Landis***

*University of Texas at Austin, **University of Texas at Austin, ***University of Texas at Austin

ABSTRACT

Large deformation and solvent migration are coupled during fracture of polymer gels. We developed a nonlinear finite element method to simulate steady-state crack growth in polymer gels, with which we calculated the J-integral as a function of the crack speed. To understand the numerical results, we developed an analytical solution for the asymptotic crack tip fields based on a linear poroelastic formulation. A strip with a semi-infinite crack in steady state was studied in details by both the linear and nonlinear models. The crack-tip fields predicted by the asymptotic solution are confirmed by the numerical results. It is found that, due to the poroelastic effect, the crack-tip stress intensity factor is generally smaller than the stress intensity factor predicted by linear elasticity model. The size of the poroelastic crack-tip field is characterized by a diffusion length scale that depends on the crack speed. For relatively fast crack growth, the diffusion length is small compared to the strip thickness, and the crack-tip field transitions to the elastic K-field at a distance proportional to the diffusion length. In this case, the energy release rate by a modified J-integral decreases with increasing crack velocity. For relatively slow crack growth, the diffusion length is comparable to or greater than the strip thickness, and the crack-tip field is confined by the strip thickness and transitions to a one-dimensional diffusion zone ahead of the crack tip. In this case, the energy release rate increases with increasing crack speed. Surprisingly, the energy release rate approaches the same limit for both fast and slow crack growth, but with a peak in between. These results suggest that, if the intrinsic fracture toughness of the gel is independent of the crack speed, the apparent fracture toughness including the energy dissipation due to solvent diffusion would be considerably greater than the intrinsic toughness and depends non-monotonically on the crack speed or the strip thickness.

Eulerian Reproducing Kernel Particle Method for Shock Modeling

Tsung-Hui Huang*, J. S. Chen**

*University of California, San Diego, **University of California, San Diego

ABSTRACT

The following issues be properly addressed in modeling shock wave propagation in hydrodynamical systems: (1) correct representation of essential shock physics, (2) stabilization of Gibbs phenomenon at discontinuity, and (3) capturing shock front with minimal smearing of moving discontinuity. In this work, we introduce a stabilized Eulerian reproducing kernel particle method (RKPM) for shock modeling. RKPM is considered herein due to its versatility in adaptive refinement and in adjusting smoothness independently to the order of completeness in the approximation. A stabilized conforming nodal integration (SCNI) is constructed with locally enriched Riemann flux, such that the essential shock physics, Rankine-Hugoniot jump condition and Lax entropy condition, are satisfied. The oscillation control is provided through the smoothed flux divergence in the SCNI framework. Furthermore, to increase the accuracy at shock front, a Monotonic Upstream-Centered Scheme for Conservation Laws (MUSCL) type flux reconstruction is introduced to achieve higher order spatial accuracy. Several numerical examples are analyzed to verify the effectiveness of the proposed framework.

A Consistent Damage Model for Structural Components of Different Materials

Wei Huang*, Zhi Zhou**

*Department of Mechanics and Engineering Structure (Wuhan University of Technology), **State Key Laboratory of Disaster Reduction in Civil Engineering (Tongji University)

ABSTRACT

Owing to the existence of varied structural components with different materials in the hybrid structures, the seismic damage failure performance and mechanisms of each component are quite different, consequently resulting in the need for a unified standard for its performance assessment. Based on the widely-used Park-Ang damage model, a consistent modification form which is suitable for structural components of different materials is proposed in the paper. The experiment statistics of various components of different materials are collected and analyzed to study the combination coefficient of the consistent damage model. Despite that the specific limit values are all calculated by the consistent damage model at the same performance levels, obvious difference exists between components of different materials. In order to build the correlation between the consistent damage model and the damage performance for components of different materials, normalized corresponding parameters are introduced to the unified damage model to specify the damage limit values at each performance level for components of different materials.

An Immersed Boundary Projection Method for Fluid-Flexible Body Interaction

Wei-Xi Huang*, Luo-Hao Wang**, Chun-Mei Xie***

*Tsinghua University, **Tsinghua University, ***Tsinghua University

ABSTRACT

An immersed boundary projection method with primitive variables is proposed for simulation of fluid-flexible body interaction. Two types of flexible bodies are considered, i.e., the 2D filament and the 3D flag. The filament's motion is constrained with the inextensible condition (while the flag is in-plane inextensible), and its interaction with the impressible fluid flow is counted by the additional momentum forcing. In the present formulation, the pressure, the momentum forcing and the tension of the filament are uniformly considered as Lagrange multipliers, which act to satisfy the divergence-free condition, the no-slip condition on the immersed boundary and the inextensibility constraint of the filament, respectively. The whole system is solved within the framework of the projection approach. For numerical implementation, a three-step approximate factorization process is proposed to decouple the tension, the momentum forcing and the pressure sequentially from the velocity fields, thus significantly reducing the computational cost. The proposed method is validated by comparing the flow-induced flapping motion with the previous studies. Both the temporal and spatial accuracies are verified and the computational cost is also measured. Results have shown good coherence with the previous studies as well as significant reduction in computational cost.

Numerical Study of Upper Airway with Obstructive Sleep Apnoea/hypopnoea Syndrome Using Large Eddy Simulation

Xiao-Wen Huang*, Ming-Jyh Chern**, Hung-Ta Hsiao***

*National Taiwan University of Science and Technology, **National Taiwan University of Science and Technology, ***National Tsing Hua University

ABSTRACT

Obstructive sleep apnoea/hypopnoea syndrome (OSAHS) is a common disorder of adult, which is caused by repeated obstruction the upper airway during sleep. The effects of OSAHS are not only the sleep quality but also the occurrence of disease such as hypertension, stroke and myocardial infarction. Apnoea-hypopnoea index (AHI) is an acceptable measure for the severity of OSAHS. Most of treatments are continuous positive airway pressure (CPAP) which is considered to be the standard treatmemt for patients with moderate-to-severe. The alternative way to prevent life-long CPAP treatment is a surgical technique. In the present study, the pre-operative and post-operative CT scan of upper airway by patients were re-constructed and converted to in vitro three-dimensional models. The transitional/turbulent flow simulations during inspiration and expiration were studied using Large Eddy Simulation (LES) in the in vitro 3D models of upper airway with a 0D lumped parameter model. Furthermore, the results show that the pressure drop of upper airway was significantly reduced after surgery and this model may be further applied for clinical evaluation in future.

Numerical Analysis of Tower Effects on Wake Flows of Floating Offshore Wind Turbine

Yang Huang*, Decheng Wan**

*Shanghai Jiao Tong University, **Shanghai Jiao Tong University

ABSTRACT

The floating offshore wind turbine (FOWT), consisting of wind turbine, floating support platform and mooring system, is quite a complex floating structure system. Accurate prediction of FOWT's coupled aerodynamic responses is of great challenge. The tower effects are usually not taken into consideration in the simulations of wind turbine aerodynamics using an actuator line model. However, it has been suggested by other researchers that including the tower effects is important in better predicting the near wake and unsteady power output. To study the influence of tower effects on coupled aero-hydrodynamic responses of FOWTs, the tower is modeled within an unsteady actuator line model in fully coupled simulations of FOWTs under variable wind and wave conditions. In the present study, the unsteady actuator line model (UALM) is embedded into in-house CFD solver naoe-FOAM-SJTU to establish a fully coupled CFD analysis tool named FOWT-UALM-SJTU for simulations of FOWTs. The blades and the tower of the wind turbine are represented by actuator lines, and the body forces applied to the flow field are calculated according to two-dimensional airfoil data. Coupled aero-hydrodynamic simulations of OC3 Hywindspar FOWT model under shear wind and regular wave conditions are conducted. The unsteady aerodynamics of wind turbines and tower effects are predicted by the UALM, and the hydrodynamic responses of floating platforms and mooring tensions can be obtained by naoe-FOAM-SJTU. From the simulations, unsteady aerodynamic characteristics including the rotor power, thrust, and detailed wake flow information are available. To better understand tower effects, the numerical results considering the tower effects are compared with previous results that the tower effects are ignored. Furthermore, both the wake flow and the aerodynamic loads are analyzed to study the influence of tower effects on coupled dynamic responses of the FOWTs. It can be found that the use of a tower model with unsteady actuator line model can improve near wake prediction accuracy. And considering the tower effects helps in more precisely predicting transient aerodynamic loads of the FOWTs.

An Innovative Fluid-Structure Computational Framework for Supersonic Parachute Inflation Dynamics

Zhengyu Huang*, Charbel Farhat**, Phil Avery***

*Stanford University, **Stanford University, ***US Army Research Laboratory, Stanford University

ABSTRACT

There is significant evidence today that the supersonic flow regime has a profound effect on the performance of a parachute [1]. Causes for even greater concern are the canopy failures observed during the inflation process in flight tests conducted by NASA for Mars landing, and the limited number of tests that can be performed for developing a better understanding of how to avoid such failures. Yet, most if not all relevant computational efforts have focused so far on developing CFD and Fluid-Structure Interaction (FSI) parachute models for the much easier to simulate post-inflation regime. To this effect, this talk will begin with a short presentation on the development of an Eulerian computational framework for evolving fluid-structure interfaces in high-speed turbulent flows, whose design is motivated by the need to simulate parachute inflation dynamics. The framework is built around an Eulerian computational model for FSI that has proven itself for the simulation of the failure analysis of submerged structures subjected to explosions and implosions [2]. It incorporates in the computations a suitable material failure model, captures the effects of strain rate and temperature, and accounts for the various interactions between the fluid subsystem. It resolves all self-contact effects of the parachute during its inflation, and tracks and resolves all evolving boundary layers using a tailored adaptive mesh refinement approach [3]. Next, the talk will proceed with the discussion of a set of preliminary simulations of a parachute's opening process performed using this computational framework, initiating from a folded sate of the of the parachute pre-inflation to the fully inflated state. Finally, the talk will conclude with an original idea about modeling different folding patterns to predict the influence of the folding pattern on the inflation process and initial, intermediate, and final stress state of the fabric when the parachute survives the inflation dynamics. 1. Hybridizable Discontinuous Galerkin from Low to High Order

Antonio Huerta*, Ruben Sevilla**, Matteo Giacomini***

*Universitat Politecnica de Catalunya, **Swansea University, ***Universitat Politecnica de Catalunya

ABSTRACT

Consistent stabilization of convection dominated problems is based in the seminal work by Hughes and coworkers. Hybridizable Discontinuous Galerkin has in recent years demonstrated its ability to solve a wide range of engineering problems. The HDG method is able to provide the optimal approximation properties that are characteristic of mixed methods, including the possibility to build a superconvergent solution, whilst retaining the advantages of DG methods. In addition, HDG methods are known to reduce the globally coupled degrees of freedom, when compared to other DG methods. Moreover, HDG is competitive compared to the traditional continuous Galerkin (CG) method and has comparable costs (in terms of floating point operations) to CG [1]. Other advantages of HDG, such as block structured information and element-by-element operations must be exploited to improve its performance compared to CG because parallelism and memory access are crucial for the final runtime. When high-order approximations are competitive, HDG can be combined with NURBS-enhanced finite element method (NEFEM) [2] to design a superior and reliable strategy where degree adaption allows to attain the desired accuracy. Moreover, in the context of computational mechanics, an alternative formulation to impose physical natural boundary conditions and strongly the symmetry of the strain tensor is proposed by means of the well-known Voigt notation for symmetric tensors. Optimal convergence of the mixed variable is retrieved for low-order elements and a novel local post-process procedure leading to a superconvergent velocity field is advanced. Other scenarios are however more suited for low-order approximations. Under this perspective, a new finite volume paradigm is presented [3]. It is called face-centered finite volume (FCFV) and is based on an HDG method with constant degree of approximation. First order convergence on both the solution and its gradient is obtained without a reconstruction of the gradients. Therefore, contrary to other finite volume methodologies, the accuracy of the FCFV method is not compromised in the presence of highly stretched or distorted elements. [1] A. Huerta, A. Angeloski, X. High-Performance Model Order Reduction Techniques for Geometrical Non-linear Problems: Application to Multi-scale Material Homogenization Problems

Alfredo Huespe*, Manuel Caicedo**, Javier Mroginski***, Sebastian Toro****, Javier Oliver*****

*CONICET, Argentine Council for Science and Technology, Argentina, **CIMNE – Internacional Center for Numerical Methods in Engineering, ***Applied Mechanical Dept., Universidad Nacional del Nordeste, Argentina, ****CONICET, Argentine Council for Science and Technology, Argentina, *****CIMNE – Internacional Center for Numerical Methods in Engineering

ABSTRACT

The purpose of this work is to generalize a version of the High Performance Reduced-Order Model (HPROM) technique, previously presented by the authors in [1], in the context of hierarchical multiscale models for heterogeneous non-linear-materials undergoing infinitesimal strains, is generalized to deal with a different range of applications. Typically, large elasto-plastic deformation problems subjected to small rotation regimes, observed in multiscale homogenization problems arising in a wide range of material modeling applications. The proposed HPROM technique uses a Proper Orthogonal Decomposition (POD) procedure to build a reduced basis of the primary kinematical variable of the micro-scale problem, defined in terms of the micro-deformation gradient fluctuations. Then a Galerkin-projection, onto this reduced basis, is utilized to reduce the dimensionality of the micro-force balance equation, the stress homogenization equation and the equivalent macro-constitutive tangent tensor equation. Finally, a reduced goal-oriented cubature rule is introduced to compute the non-affine terms of these equations [2]. The work is focused on the numerical assessment of the HPROM technique. The numerical experiments are performed on a micro-cell simulating a randomly distributed set of elastic inclusions embedded into an elasto-plastic matrix. This micro-structure is representative of a typical ductile metallic alloy. The HPROM technique applied to this type of problem displays high computational speed-ups, increasing with the complexity of the finite element model. We conclude that this technology is adequate for applications in material modeling involving two length scales, using full 3D cells with refined micro-structural details. [1] J. Oliver, M. Probing Mechanics at the Scales of Cells and Tissue via Optical Coherence Tomography

Nicholas Hugenberg*, Assad Oberai**, Li Dong***

*Rensselaer Polytechnic Institute, **University of Southern California, ***University of Texas at Austin

ABSTRACT

In this talk we will describe new developments from the field of Optical Coherence Elastography (OCE) that have enabled the mapping of the mechanical properties of cells, clusters of cells, and tissue. OCE affords a spatial resolution of about 10-20 microns, and a field of view of about 2-5 millimeters. This makes it ideal for quantifying the mechanical microenvironment for diseases like cancer and atherosclerosis. We will focus on new computational methods within OCE that have made this possible. These include new adaptive grid methods for solving inverse problems, and methods for solving the nonlinear inverse elasticity problem.

From (HHT)-Alpha to Omega?

Gregory Hulbert*

*University of Michigan

ABSTRACT

It has been more than 40 years since the HHT-alpha time integration method was published in one of the early volumes of Earthquake Engineering and Structural Dynamics. It is, without doubt, the most cited method for structural dynamics, with the possible exception of Newmark's seminal work in the 1950's. In this presentation, we will articulate why the HHT-alpha has maintained its prominence. We will also propose a lingua franca, using the works Tom Hughes as inspiration, for researchers who endeavor to introduce new time integration methods, so that such contributions to the time integration field can be correctly classified, categorized and recognized.

Modeling Thrombus Formation in Abdominal Aortic Aneurysms

Jay Humphrey*, Druv Bhagavan**, Paolo Di Achille***

*Yale University, **Yale University, ***Yale University

ABSTRACT

Over 75% of abdominal aortic aneurysms develop an intraluminal thrombus, that is, a blood clot. Although there is controversy surrounding the potential roles of thrombus in the natural history of aneurysms, increasing evidence suggests that a thrombus releases biomolecules can contribute to degradation of the aneurysmal wall, thus leading to continued enlargement and increased risk of rupture. There is, therefore, strong motivation to predict where and when a thrombus might form in particular patients [1]. We suggest that thrombus initiates when two hemodynamic factors co-localize in space and time. First, the endothelial cell layer that lines the inner surface of the aorta and the aneurysm must be rendered susceptible to platelet attachment. Second, this susceptible region must be presented with activated platelets that can attach and aggregate. We suggest further that once a thrombus initiates, it will continue to grow within the flow field until hemodynamic forces become sufficient to prevent any further platelet attachment or protein adsorption. We use open source software, SimVascular, to solve the requisite Navier-Stokes equations and a custom Lagrangian particle tracking code to estimate platelet motions. Based on our computational findings, we propose two scalar hemodynamic metrics to predict both thrombus formation and deposition in patient-specific models of abdominal aortic aneurysms and show that predictions compare favorably with results obtained from medical imaging [2,3]. Finally, we consider hemodynamics within a host of idealized model aneurysms and use kriging to explore parametrically the effect of five different morphological features of the infrarenal aorta and associated aneurysm on thrombus formation and identify potential clinical predictors of future thrombus accumulation. Construction of Simplified Models for Crack Propagation in Random Heterogeneous Media

Darith Hun*, Johann Guilleminot**, Julien Yvonnet***, Michel Bornert****

*Laboratoire Modélisation Simulation Multi Echelle (MSME), **CEE, Duke University, ***Laboratoire Modélisation Simulation Multi Echelle (MSME), ****Laboratoire Navier

ABSTRACT

In this work, a method is proposed to describe cracks in random heterogeneous media. To avoid describing all heterogeneities, we propose a simplified model which takes into account local fluctuations due to both elasticity and damage parameters variability through a filter-based technique. First, we develop a filter-based homogenization technique using moving windows to construct a simplified model where heterogeneities are described with a larger wavelength than the fully described model. For elastic parameters, the local elastic properties are directly provided by the filter method, while the damage parameters are obtained by inverse approach of crack propagation in the simplified model with respect to the direct numerical simulation in the heterogeneous medium. The phase field method [1,2] is employed for initiation and crack propagation simulations. A stochastic model is constructed to generate realizations of the simplified model which is able to reproduce statistically both mechanical response and crack paths. The random elastic characteristics of the simplified model can be identified by a stochastic descriptor based on the maximum entropy principle introduced in [3], and used for generating the local elastic properties of the simplified model over arbitrary meshes, which can be locally refined in the neighborhood of the crack path. Regarding damage parameters, an optimization problem is solved, ensuring that the statistical mechanical response is consistent with the direct numerical simulations in the heterogeneous medium. The technique is illustrated through problems involving crack propagation in fiber-reinforced composites. Non-conforming Finite-element Method for Cardiac Electrophysiology Simulations

Daniel Hurtado*, Javiera Jilberto**

*Pontificia Universidad Católica de Chile, **Pontificia Universidad Católica de Chile

ABSTRACT

The study of cardiac disease in the human heart has greatly benefitted from computational tools in the last decade. In particular, the field of computational electrophysiology has enabled in-silico studies of arrhythmogenesis, cardiac failure and therapy design that are otherwise impossible to perform in-vivo. Despites these advances, the computational effort associated to whole heart simulations remains prohibitively, as accuracy of such simulations impose strict discretization demands both in space and time. For example, in order to recover accurate conduction velocities and wavefront shapes in cardiac simulations, the mesh size in Q1 finite-element formulations cannot exceed 0.1 mm [1]. Here we propose a novel non-conforming finite-element scheme for solving the cardiac electrophysiology equations, suitable for arbitrary cardiac domains [2]. We show that the proposed spatial interpolation scheme results in more accurate wavefront shapes and lower mesh-dependence in the conduction velocity than traditional Q1 formulations, while retaining the same number of global degrees of freedom. As a result, coarser discretizations of cardiac domains can be employed in simulations without significant loss of accuracy, thus reducing the overall computational effort. We demonstrate the applicability of the proposed scheme in the study of cardiac arrhythmogenesis by simulating the generation of spirals in cardiac tissue and heart biventricular domains, and the effect of non-conforming schemes in improving the accuracy-efficiency trade-off of cardiac simulations. Disbonding of Sandwich Panels Exhibiting Fiber Bridging Accounting for Mode Mixity

Daniel Höwer*, Bradley A. Lerch**, Brett A. Bednarcyk***, Evan J. Pineda****, Stefanie Reese*****, Jaan-Willem Simon******

*Institute of Applied Mechanics, RWTH Aachen University, 52074 Aachen, Germany, **NASA Glenn Research Center, Cleveland, OH 44135, USA, ***NASA Glenn Research Center, Cleveland, OH 44135, USA, ****NASA Glenn Research Center, Cleveland, OH 44135, USA, *****Institute of Applied Mechanics, RWTH Aachen University, 52074 Aachen, Germany, ******Institute of Applied Mechanics, RWTH Aachen University, 52074 Aachen, Germany

ABSTRACT

Due to their very high stiffness to weight ratio, sandwich panels with honeycomb core and carbon fiber reinforced plastic facesheets are becoming increasingly popular in aerospace applications. However, the honeycomb topology also provides modelling challenges when the disbonding between facesheet and sandwich core is to be modelled [1] [2]. The authors have previously shown that the disbonding between the facesheet and the honeycomb core of said sandwich panels cannot be accurately described by established cohesive zone formulations and a novel formulation was developed [3]. The formulation requires a number of parameters which can be extracted from experiments by combining load displacement data on the one hand and digital image correlation strain data on the other hand. The parameter set was obtained for the interface between IM7/8552–1 prepreg tape and Hexcel 5052 aluminum honeycomb core bonded with FM 300K film adhesive, which constitutes the baseline design of the cargo fairing of the NASA Space Launch System (SLS). The novel formulation is comprised of two cohesive components, one of which is related to the initial interface traction while the other one is related to the bridging tractions in the wake of the crack tip. So far, this formulation has only been used to describe the mode I dominated disbonding of single cantilever beam specimens. Subsequently, the formulation has been extended to account for mixed-mode disbonding through a potential-based approach. Results obtained with the mixed-mode formulation are presented herein. Key words: Aluminum wheel, Inflated tire, Dynamics, Impact.

Abstract. The design process of aluminum wheels has become one of the critical matters in order to improve convenience and safety in an automobile vehicle. Since the impact test has been one of the most important subjects for the strength requirements of the aluminum wheel, the 13 degree lateral impact test was regulated as standard test by SAE. Furthermore, automobile makers compel the 90 degree vertical impact test in recent years. Hence, wheel product makers have executed not only 13 degree impact test but also 90 degree test. While these impact tests caused the large amount of costs and human resources, the necessity of preliminary investigation was highly demanded on the design stage. Therefore, it is needed to analyze the wheel impact test by using CAE technology. Also, it is demanded for development of accurate analysis results with comparing to experimental data. In this paper, we explored the use of Abaqus/Standard and Explicit for impact analysis of aluminum wheel with inflated tire. The analysis model consisted of an aluminum wheel and complicated tire structure. The process of inflation of tire was executed by Abaqus/Standard as an implicit method, subsequently the inflation conditions were imported to Abaqus/Explicit dynamic analysis for impact tests. The results of impact analyses were compared with the empirical results; the performance and accuracy were examined. In addition, we investigated the incompressible effect of tire material with Poisson's ratio. Our proposed method provides new structural designs that prove the potential of the concept to improve the strength and durability of the aluminum wheel.

1 INTRODUCTION

To improve convenience and safety of automobile vehicles, impact tests for Aluminum wheel

have been required for the guarantee of safety condition. SAE (SAE, 2003) regulates the 13degree lateral impact test which is shown in Figure 1. This test aims for side contact to a curbstone. The target is the lateral stiffness of total tire system.

But in recent years, Automobile manufacturers require more critical test which is 90 degree vertical impact test shown in Figure 2. The target is the vertical stiffness of total tire system. By contrast, those impact experiments require high cost including human resources.

To achieve a higher level of design, the practical use of CAE system is significant. In this paper, we discussed the application of impact analysis of aluminum wheel. The analysis model was composed of aluminum wheel and tire structure. The tire structure model was naturally inflated with pressure load by Abaqus/Standard, and the results of implicit analysis were imported to Abaqus/Explicit for the dynamical impact analysis afterward. Both results of 13 and 90 degree impact analyses were compared with the experimental data; the performance and accuracy were examined.

Moreover we investigated the effect of Poisson's ratio, the incompressibility is important issue not only rubber tire quality but also the total stiffness of tire and wheel. The differences of Poisson's ratio caused severe results of permanent deformation of the wheel.

We emphasize that our proposal analysis methods can help us design more robust and sophisticated Aluminum Wheel.

Figure 1. 13 degree falling test is regulated by SAE.

Figure 2. 90 degree falling test.

2 FE MODEL

2.1 13 degree model

To meet the SAE standard requirements shown in Figure 3, FEA model was assembled with four parts in our modeling study. Figure 4 shows the 13 degree impact test model. The model consisted of Aluminum wheel, test jig, rigid striker and tire.

This analysis model was formed with two steps. In the first step, the tire was statically inflated to regulated 200kPa pressure; this process was analyzed by Abaqus/Standard. In the second step, the impact dynamic analysis was executed by Abaqus/Explicit. Naturally, the first step static results were imported to the second dynamic analysis as an initial condition.

In the first simulation, the inflation step was performed on the half model of three dimensional tire. Figure 5 shows the detailed structure of tire. The main part of tire was modeled with three dimensional hexahedron solid elements which were applied to the simple Neo hookean hyperelastic material. The belts and carcass were modeled by reinforced bar of surface elements embedded in continuum elements. Furthermore, the steel bead was modeled with three dimensional solid elements. The most important wheel model was generated as 10nodes modified tetrahedron solid element. The sample test piece for the stress-strain behavior was cut out from the formed wheel.

In order to set clear boundary and loading conditions in the dynamic procedure, the FE model involved test jig part as Figure 4. In addition, the test jig model was supported by connector elements which figured the rubber inelastic behavior. The initial velocity which was assumed the free dropping above 230mm height was applied to the striker. This height is regulated by SAE.

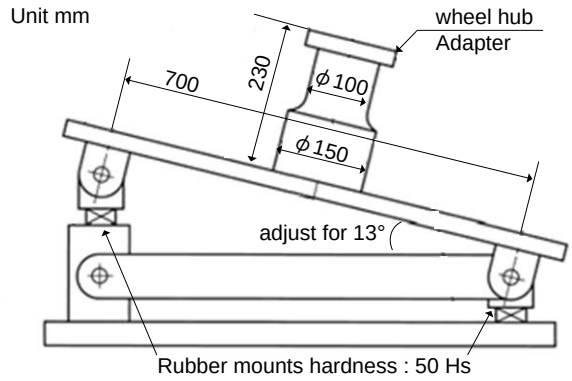

Figure 3. 13 degree falling test apparatus.

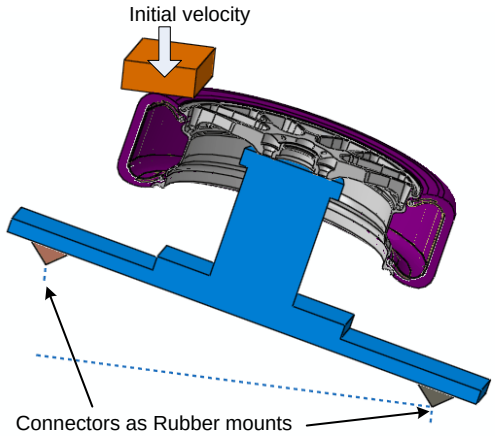

Figure 4. 13 degree FE analysis model.

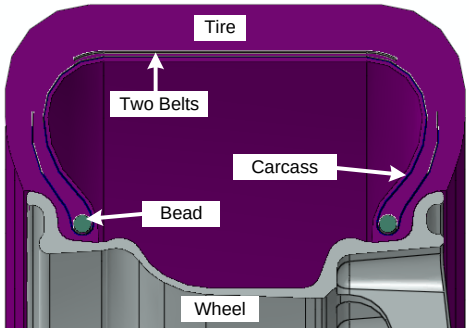

Figure 5. Section structure of tire.

2.2 90 degree model

Figure 6 shows the 90 degree analysis model. This model was formed with two steps as same as 13 degree analysis model. The first step was tire inflation analysis by Abaqus/Standard, following, the impact dynamic analysis was executed by Abaqus/Explicit at the second step. The tire pressure varied with the size of wheel in the actual test. In this analysis, the tire pressure was applied to 260kPa.

The tire structure and the material of wheel were same as 13 degree model. The entire fixed boundary condition was applied on the center face of the wheel. The initial velocity which was assumed the free dropping above 101.6mm height was applied to the striker under the explicit dynamic analysis.

The contact conditions with friction phenomena were invoked between tire and wheel, and also between striker and tire. While another contact condition was applied to whole area such as tire's self-contact condition in different coefficient of friction.

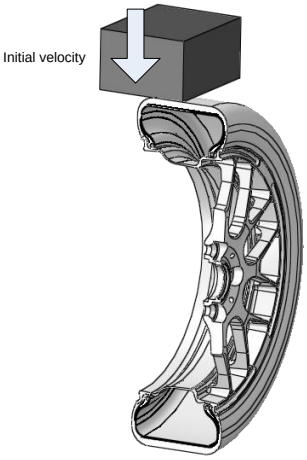

Figure 6. 90 degree FE analysis model.

Table 1. Model size

Part	Element type	Number of nodes	Number of elements
Wheel	C3D10M	150249	86465
Tire	C3D8R	10080	6958
Bead	C3D8R	1188	520
Belt	SFM3D4R	2040	1848
Carcass	SFM3D4R	2880	2769
Base (13 degree model only)	C3D10M	59455	38968

2.3 Model size

Table 1 shows the typical model size and element types of each parts. The material of wheel was Aluminum alloy which was composed from Al-Mg-Si. The wheel was modeled with quadratic tetrahedron element (C3D10M).

The tire was modeled as a slightly compressible hyperelastic material with reduced integration linear hexahedral element (C3D8R).

The fiber reinforcement was modeled as a linear elastic material at the parts of belts and carcass with surface element (SFM3D4R) embedded into the tire part.

The base part used in only 13 degree analysis was modeled as ordinary steel with quadratic tetrahedron solid element. The material was just linear elastic.

3 RESULTS

3.1 13 degree model

In order to examine our proposal model, two analyses were performed. One analysis was with tire model, and the other was without tire model. The section outlines of original shape and deformed configurations are shown in Figure 7. The thin line shows the original shape, the black solid line shows the deformed shape which is real experimental result, the coincided blue line indicates the result of FEA model with inflated tire, and the last red line which is depicted at the lowest position indicates the result without tire. The result of FEA model with inflated tire coincided with the experimental result. On the other hand, if the tire model was omitted, the permanent displacement result was calculated larger than it with tire model. These results insist that even in the 13 degree analysis case the tire model is essential.

Figure 8 shows the principal strain contour of dynamic implicit analysis, while Figure 9 shows the real experimental result which had the crack on the side of spoke. In this investigation, we adopted the trial wheel model for reducing weight. As Figure 8 describes, the analysis model was able to estimate the actual crack area.

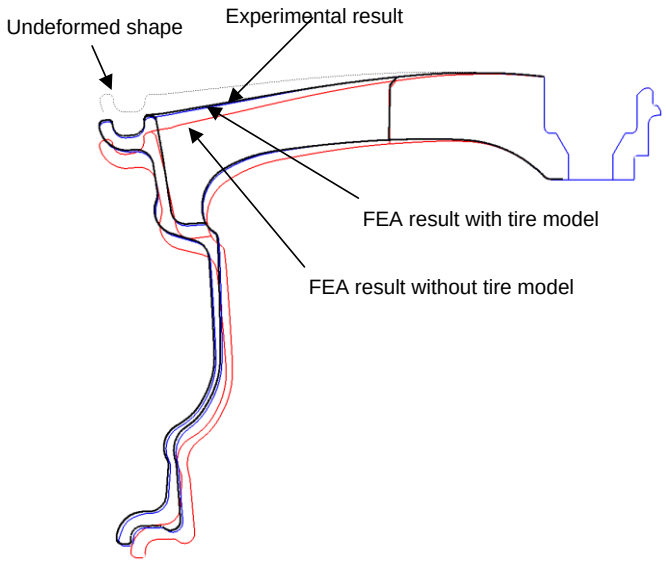

Figure 7. Comparison of deformed section outlines.

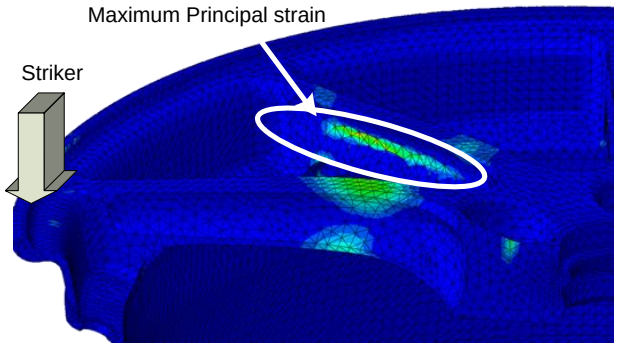

Figure 8. Maximum principal strain at thin spoke wheel model.

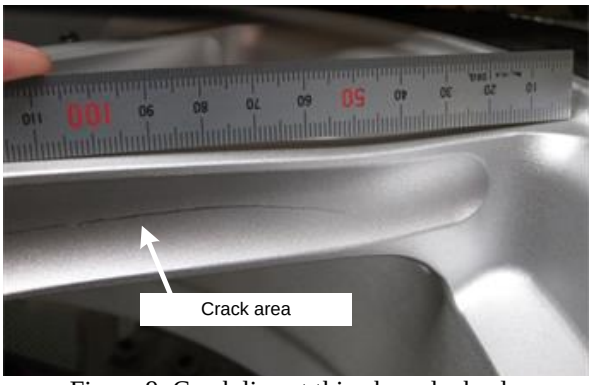

Figure 9. Crack line at thin shaped wheel on on experimental test.

3.2 90 degree model

3.2.1 Deformation

Figure 10 and 11 show the deformation both tire and wheel. This frame illustrates the maximum displacement at instance. Because of incompressibility of rubber material, the wheel suffered from large plastic deformation.

Figure 12 shows the mirror deformation configuration, while Figure 13 shows the deformation of experimental test. The analysis acquired the same amount of deformation and figure.

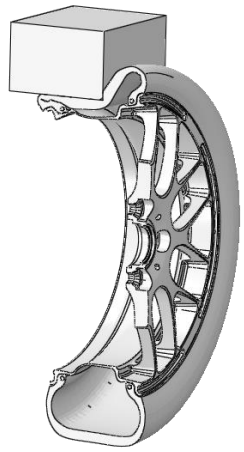

Figure 10. Whole deformation figure.

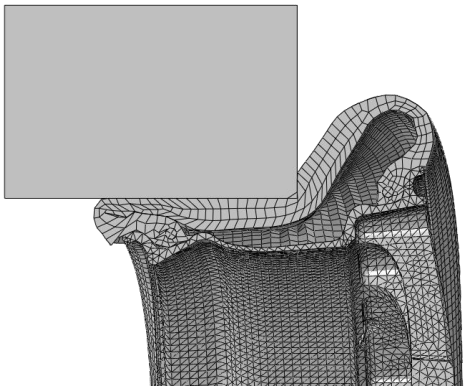

Figure 11. Maximum deformation of tire and wheel.

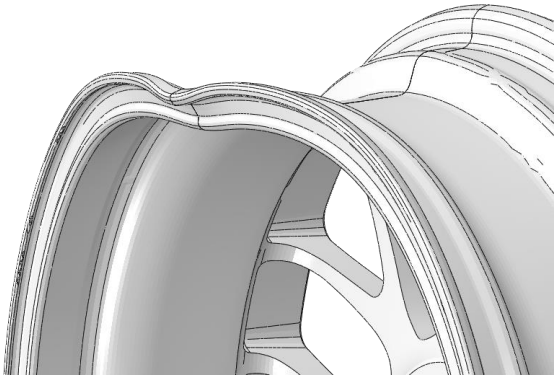

Figure 12. Mirror deformation configuration.

Figure 13. Result of experimental test.

3.2.2 Poisson's effect

Figure 11 revealed the compressive stiffness is the most significant for the 90 degree drop analysis. Therefore we investigated the effect of Poisson's ratio. Table 2 shows the analysis results with various Poisson's ratio. If Poisson's ratio became nearly incompressible behavior, the large permanent displacement was invoked as shown in Figure 14.

If we apply the nearly incompressible material on the Explicit analysis, the time step will be smaller than normal condition in expectations because of the Courant condition. Nevertheless Table 2 showed that all of the calculation time was about same order. It was thought that the reason was because the mesh size of the wheel was much smaller than rubber.

Table 2. Classification of Poisson's ratio. Maximum displacement of wheel and calculation time.

Case	Poisson's ratio	Maximum displacement[mm]	Wall time [hh:mm]
1	0.499	36.36	33:01
2	0.49	31.89	21:44
3	0.48	29.90	32:47
4	0.47	28.84	32:39

Figure 14. Contour plot of deformed wheel which was applied Poisson's ratio as 0.499.

4 CONCLUSION

We established the FE analysis model for 13 and 90 degree Aluminum impact test with inflated tire. Abaqus has the seamless connection between implicit and explicit procedures. This function is substantial for integrating impact analysis with inflated tire.

The study of 13 degree model argued the need for modeling of tire. The analysis result showed large displacement of wheel without tire model.

The result of 90 degree model depicted same amount of deformation and shape for a real examination. Furthermore, the Poisson's ratio indicated the importance of incompressibility of tire material.

Rx-FEM Prediction of Delamination Migration in Multilayered Tapered Composite Beam Specimens under Fatigue Loading

Endel Iarve*, Hari Adluru**, Kevin Hoos***

*University of Texas at Arlington, **University of Texas at Arlington Research Institute, ***University of Texas at Arlington Research Institute

ABSTRACT

Multilayered Clamped Tapered Beam Specimen (CTBS) designed by Advanced Composite Project Team at NASA Langley Research Center (LaRC) in Hampton, VA [1] is considered. This specimen contains a ply tapering feature characteristic of aerospace applications and allows studying the matrix crack initiation from pristine condition as well as delamination initiation and evolution including migration from one interface to another. Discrete Damage Modeling (DDM) method termed Regularized Extended Finite Element Method (Rx-FEM) described in Ref. [2] was used in the present work. The Rx-FEM allows modeling the displacement discontinuity associated with individual matrix cracks in individual plies of a composite without regard to mesh orientation by inserting additional degrees of freedom in the process of the simulation. A regularized crack surface Heaviside step function is used in finite elements, which are duplicated along the crack path. The propagation of the mesh independent crack is then performed by using cohesive zone method where the displacement jump is computed as spatial separation of the duplicated elements and the crack surface energy obtained through volume integration by using the gradient of the crack surface Heaviside step function. The methodology has been extensively applied to strength prediction of coupon and subelement level composite structures under tensile, compressive and more recently fatigue loading in Ref [3]. The CTBS simulations were performed simultaneously with experiments conducted by NASA LaRC. The static peak load predicted by using the transverse strength value obtained from the three point bend test method was in good correlation with the experiment whereas the peak load predicted by using values resulting from tensile testing of 900 coupons was lower than experiment. Two load amplitude levels of 0.9 and 0.79 of the static peak strength were selected for R=0.2 constant amplitude fatigue loading. The delamination migration location and cycle count were predicted and compared with experimental data. Quantifying the Size Effect in Localized Failure of Composite Structures through Coupled Probability-Multiscale-Mechanics Computations

Adnan Ibrahimbegovic*, Xuan-Nam Do**, Emir Karavelic***, Mijo Nikolic****

*University of Technology Compiegne, France, **University of Technology Compiegne, France, ***University of Technology Compiegne, France, ****University of Technology Compiegne, France

ABSTRACT

This paper deals with important challenge on quantifying durability, life-time integrity and safety against failure of massive composite structures under extreme conditions. The illustrative applications come from the area of energy production systems, with both currently dominant nuclear (nuclear power plant) or renewable energy sources (wind turbines and hydro-turbines). Special attention is given to costly massive structures with 'irreplaceable' components, which are characterized by a number of different failure modes that require the most detailed description and interaction across the scales. We would like to significantly improve the currently dominant experimental approach, and thus accelerate innovations in this domain. The main objective is development of novel Heterogeneous2 Multiscale Method capable of representing strain field heterogeneities induced by evolution (and interaction) of localized failure mechanisms in massive structure, pertaining to micro scale (FPZ-fracture process zone), macro scale including softening (macro cracks) and non-local macro scale (bond-slip for long fiber reinforcement). The objective of Heterogeneous2 Multiscale Method is also to provide capabilities for quantifying the risk of premature localized failure through probability description of initial defects (microstructure heterogeneity) and uncertainty propagation through scales. The novel scientific concept to be explored pertains to multiscale formulation and solution of coupled nonlinear mechanics-probability problem replacing the standard homogenization approach that can only provide average (deterministic) properties of heterogeneous composites. This concept is of interdisciplinary nature with Mechanics (defining probability distribution) and Applied Mathematics (providing uncertainty propagation) combined in order to capture the influence of heterogeneities and fine scale defects on premature failure. The most important challenge concerns the ability to provide the sound, probability-based explanation of size effect (with different failure modes observed for different size specimens and real structure built of the same composite materials). The biggest potential gain concerns changing the validation procedures for massive structures that are beyond the size suitable for testing at present. The scientific gains concern providing the Heterogeneous2 Multiscale Method that connects computations with design studies (optimization), testing (identification) and safety verification (monitoring) of massive composite structures. The scientific gains also concern further placing the proposed method within multiphysics framework, along with the original use of goal oriented error estimates to provide sufficiently reliable interpretation of extreme conditions (e.g. fluid or heat flow) and the code-coupling software implementation to quickly integrate existing simulation codes within such a framework.

ABSTRACT

Model order reduction techniques are an appealing tool to alleviate prohibitive computational efforts. Indeed, POD-like methods, where a set of snapshots are used to construct an a posteriori reduced basis, are proved to be effective when only few modes are carrying most part of the information. PGD-like methods can be highlighted as a priori method, where a specific tensorial separated representation is used. By means of the last technique, parametrique solutions are obtained in a very efficient way, just like the possibility of uncoupling spatial dimensions i.e. in-plane-out-of-plane separated representation. Even though a priori model order reduction methods are a very powerful tool, the number of modes required to represent accurately a given solution could increase drasticly depending on the structure of the tensorial separated representation. For instance, a transient heat problem with a spatial moving source is not optimal when space and time are separated independently. Therefore, several ideas are tested in the present work. Firstly, PGD will be used as a tool to provide a local enrichment of a global polynomial approximation, always under the constraints of the partition of the unity. Secondly, the direction of the modes can be introduced as a extra coordinate. Hence, the solution becomes more separable, requiring less number of modes, by properly selecting the direction of the separated representation. However, if the solution is highly non linear, the best direction will not be the same everywhere, requiring a different axis rotation locally. Thus, techniques to select the best local direction just like interpolation of non-cartesian domains are studied.

ABSTRACT

Development of Meshfree Particle Method for Solid Mechanics Masakazu Ichimiya[1], Nobuki Yamagata[1],and Pedro V. Marcal2 1 Advanced Creative Technology Co., Ltd., 2 MPACT Corp. Key Words: MeshFree Particle Method, SSPH, Solid Mechanics, Elastostatic. The meshfree method has developed greatly as a solution to partial differential equations. Among them, the Meshfree particle methods, such as SPH were successfully applied mainly to hydrodynamics. Considering coupling of solid with fluid dynamics, etc., it is important to apply the meshfree particle method to solid mechanics as well. Thus, the meshfree particle method was applied to solid mechanics. 1. Although the conventional SPH is a dynamic analysis method and applied to impact destruction and the like, there were some difficulties in application to static analyses which account for most structural problems. Therefore, the SSPH method was selected as a meshfree particle method applicable to solid mechanics, and it was formulated by incorporating material and geometrical nonlinearities in addition to elastic mechanics. 2. In order to evaluate its applicabilities, the objects to be analyzed were general such as bending of beam, bending of flat plate, and stress concentration problem such as plate including circular hole. Also, thermal stress analysis was performed. 3. As a result, it was found that the mesh free particle method SSPH can be applied with high accuracy on the solid mechanics including elastostatic.

ABSTRACT

Extensive usage of numerical simulations is desirable for estimating responses of sophisticated heterogeneous models in earthquake problems. As the boundary conditions and geometric shape have strong effects on numerical results, use of finite element analysis methods is desirable. However, because the domain size is huge and the required resolution high, degrees of freedom are in the order of 10$^{8-12}$; it is difficult to conduct finite element analysis using such large models. Thus, unfortunately, simplified models are conventionally used. To realize finite element analysis with such large models, researches enhanced by HPC have been conducted. Our developed algorithm enhances computational capability and enables us to conduct nonlinear wave finite element analysis with 1 trillion degrees of freedom, and static linear finite element analysis with 2 trillion degrees of freedom. Further improvement is conducted towards HQC in earthquakes with GPU and AI (e.g. multiple analysis for huge models, considering the uncertainty of the model/scenario).

ABSTRACT

Lagrangian-based methods using particles are established methodologies which rely on the goodness of particles for solving the convective term of transport equations. Despite having shown impressive results for some particular applications and presenting promissory potential for parallel architectures, the efficiency of particle-based methods solving the incompressible Navier-Stokes equations currently does not justify its massive use in replace of classical Eulerian methodologies. Strategies such as PFEM-2 [1] have decreased the huge computational cost of particle methods, but mainly because of the low order schemes employed. This work presents the first proposal of a second order accurate particle method in both time and space for solving incompressible flows equations within a Lagrangian formulation. This methodology consists on reinterpreting the convective term of any transport equation as a source term estimated with particles. An updated version of the eXplicit Integration Following the Acceleration and Streamlines (X-IVAS) method [2] is used and a second order projection scheme is employed to transfer data from the particles to the mesh. In the case of incompressible flows, the modified momentum equation is used as velocity predictor without modifying the original rate of convergence of the Eulerian solution but improving the numerical approximation of the convective term. With the aim of presenting the methodology and particle-mesh interaction, firstly the solution of scalar transport equations is shown. Then, incompressible flow problems are solved where the rate of convergence of the method is assessed experimentally and the need of iterating the X-IVAS during velocity-pressure coupling is revealed. The implementation on the open source platform OpenFOAM allows employing general polyhedral meshes and obtaining reliable computing times comparisons. Results reveals that, for the analyzed cases, the current method is able to obtain the same or lower level of error than a fast Eulerian alternative, but saving considerably total computing time. A New Numerical Approach to the Solution of Partial Differential Equations with Optimal Accuracy on Irregular Domains and Embedded Uniform Meshes.

Alexander Idesman*

*Texas Tech University

ABSTRACT

A new numerical approach based on the minimization of the local truncation error is suggested for the solution of partial differential equations. Uniform Cartesian meshes are currently used for the space discretization. Similar to the finite difference method, the form and the width of the stencil equations are assumed in advance. A discrete system of equations includes regular uniform stencils for internal points and non-uniform cut stencils for the nodes located close to the boundary. The unknown coefficients of the discrete system are calculated by the minimization of the order of the local truncation error. The main advantages of the new approach are a high accuracy and the simplicity of the formation of a discrete (semi-discrete) system of equations for irregular domains. For the regular uniform stencils, the stencil coefficients can be found analytically. For non-uniform cut stencils, the stencil coefficients are numerically calculated by the solution of a small system of linear algebraic equations (10-20 algebraic equations). In contrast to the finite elements, there is no necessity to calculate by integration the elemental mass and stiffness matrices that is time consuming for high-order elements. As a mesh, the grid points of a uniform rectangular (square) mesh as well as the points of the intersection of the boundary of a complex irregular domain with the horizontal, vertical and diagonal lines of the uniform mesh are used; i.e., in contrast to the finite element meshes, a trivial mesh is used with the new approach. Changing the width of the stencil equations, different high-order numerical techniques can be developed with the new approach. Currently the new technique is applied to the solution of the time dependent wave and heat equations and the time independent Laplace equation. The theoretical and numerical results show that for the width of the stencil equations equal to that for the linear quadrilateral finite elements, the new technique yields the fourth order of accuracy of the numerical results on irregular domains for the considered partial differential equations (it is much more accurate compared with the linear and even quadratic finite elements at the same number of degrees of freedom).

Computational Challenges Towards Exascale Fusion Plasma Turbulence Simulations

Yasuhiro Idomura*

*Japan Atomic Energy Agency

ABSTRACT

Turbulent transport is one of key issues in fusion science. To address this issue via a five dimensional (5D) gyrokinetic model, the Gyrokinetic Toroidal 5D full-f Eulerian code GT5D has been developed. On the K-computer, inter-node parallelization techniques such as multi-dimensional/-layer domain decomposition and communication-computation overlap were developed, and strong scaling of GT5D was improved up to 73,728 nodes [Idomura et al., Int. J. HPC Appl. (2014)]. This computing power enabled us to study ITER relevant issues such as the plasma size scaling of turbulent transport. However, extensions of GT5D towards burning plasmas including kinetic electrons and multi-species ions require exascale computing. Under the post-K project (Japanese exascale computing project), we have developed computing techniques for the next generation computing platforms based on many core processors. In this talk, we discuss computational challenges related to complicated intra-processor memory hierarchy and limited inter-node communication performance compared with accelerated computation. The former issue is addressed by optimizing data access patterns of a stencil kernel on each many core architecture, and high performance gains are obtained on several many core architectures [Asahi et al., IEEE-TPDS (2017)]. The latter issue is resolved by using advanced communication-avoiding Krylov methods, which enables an order of magnitude reduction of collective communications [Idomura et al., ScalA17@SC17]. By applying these novel computing techniques, the performance of GT5D is dramatically improved on the Oakforest-PACS, which consists of 8,208 KNLs.

*Tokyo Institute of Technology, **Tokyo Institute of Technology, ***Tokyo Institute of Technology

ABSTRACT

Tetrahedral elements are widely used in many practical finite element (FE) analysis because complex shapes cannot be meshed into high-quality hexahedral meshes. However, classical tetrahedral elements have issues in accuracy, robustness and stability especially for nearly incompressible materials. Although the u/p hybrid formulation with tetrahedral elements are typically chosen as general methods for nearly incompressible materials, they cannot be directly applied to explicit dynamics. Therefore, highly accurate explicit dynamics for complex shapes of nearly incompressible materials are still open problems. Recently, smoothed finite element methods (S-FEMs), which are known as the highly accurate four-node tetrahedral (T4) formulations, have been proposed and gather attention. S-FEMs are purely displacement-based formulation unlike u/p hybrid formulation, and thus can be easily extended to the explicit dynamics. Onishi et.al. have proposed an advanced S-FEM called F-bar aided edge-based smoothed finite element method with T4 element (F-barES-FEM-T4) to realize stable and accurate FE analysis for nearly incompressible materials. F-barES-FEM-T4 shows the excellent accuracy without locking and pressure checkerboarding in the large deformation static and quasi-static implicit analysis. Meanwhile, in dynamic analysis, it is reported that F-barES-FEM-T4 has unstable deformation mode and causes energy divergence. The authors have proposed an stabilized F-barES-FEM-T4 in dynamic analysis called SymF-barES-FEM-T4. SymF-barES-FEM-T4 achieves removing instability and realizing accurate long-term dynamic analysis only by modifying the definition of B-matrix of internal force vector. However, the performance evaluations were restricted to too simple or unpractical scenarios without contact analysis and more practical evaluations are still needed. The aim of this research is to evaluate the performance of SymF-barES-FEM-T4 in contact-included scenario. Some examples reveal that SymF-barES-FEM-T4 realize stable contact analysis without any issues such as contact force oscillation.

Investigation of Elastoplastic Deformation Behavior of Polycarbonate Using Molecular Dynamics Simulation

Daiki Ikeshima*, Kazunori Miyamoto**, Akio Yonezu***

*Chuo University, **Chuo University, ***Chuo University

ABSTRACT

Polycarbonate (PC) is an important engineering polymer that has been used as the structural material in a wide range of applications. In polymer materials, the molecular structure is very crucial for their macroscopic mechanical properties. This study investigated the elastoplastic deformation mechanism at molecular structural level during uni-axial tensile loading and nano indentation by using molecular dynamics (MD) simulation. In this study, to drastically improve computational efficiency, coarse -grained (CG) approach for MD simulation is newly established. In other words, a new CG force field is developed for PC based on full-atom MD simulations [1]. In this approach, the four functional groups (phenylene, isopropylidene, phenylene and carbonate) in a molecular chains are recognized to be four coarse grained particles. First, uni-axial tensile deformation is performed using the newly developed force field. During uni-axial tensile deformation, the polymer chains undergo elastic deformation, and are followed by plastic deformation. The deformation mechanism at molecular structural level (molecular topology) is investigated. Especially, it is found that changes in the bond stretch, bending angle and torsional angle of molecular chains during uni-axial tensile deformation are quantitatively examined. It is found that their potential energy significantly changes with respected to the applied tensile strain. Based on the variation of potential energy, we discussed mechanism of yielding onset and plastic deformation. Especially, change of potential energy of bending angle is raised at yielding. Next, nano indentation test is performed in MD simulation. During a loading process, reaction force (which comes from the interaction force between indenter probe and polymer surface) shows increasing with respected to the penetration depth. Energy variations associated with bond stretching, bending and torsion are further investigated to obtain useful insights of the deformation mechanism. It is found that their potential energy significantly changes with respected to the penetration depth. Based on the variation of potential energy, the mechanism of yielding onset and plastic deformation during AFM nano indentation test is also discussed. Reference [1] D. Powder Jet Additive Manufacturing Modeling for Residual Deformation and Stress Prediction

Athanasios Iliopoulos*, John Michopoulos**, John Steuben***, Andrew Birnbaum****

*U.S. Naval Research Laboratory, **U.S. Naval Research Laboratory, ***U.S. Naval Research Laboratory, ****U.S. Naval Research Laboratory

ABSTRACT

The rapid interest in Additive Manufacturing (AM), alongside the undesired effects it introduces on the fabricated parts, have motivated the need to develop tools for the prediction and correction of such effects. In the rush to accommodate the pace the end users and the industry dictate in their eagerness to adopt AM, most of the tools developed have been designed using semi-empirical simulation approaches and in many cases are dependent on non-deterministic adjustment requirements against inconsistencies between the predicted and fabricated parts qualities. In this talk we present a new approach that is based on an accurate point-by-point energy and mass deposition model, that closely follows the process in powder jet technologies. The computational methodology is implemented using a pre-defined mesh, that follows the powder jet g-code program, and enables mass and thermal energy deposition using spatiotemporally dependent properties by properly activating material property transitions. The model fully couples thermal physics and structural mechanics. An implementation of the proposed computational infrastructure is presented for the COMSOL Multiphysics finite element analysis software. The process is demonstrated for a thin walled square box geometry that was also manufactured using a powder jet system. The results of the simulations are evaluated against their ability to predict deformation and residual stresses, alongside thermocouple data that was captured during the fabrication of the part.

Key words: AMR Method, Impulse Response , Acoustic Impedance

Abstract. This paper presents an impulse response analysis method considering acoustic impedance for reproducing arbitrary reflection and a transmission condition. The CIP method using adaptive mesh refinements (AMR) is employed the descretization of wave equation. The pseudo impulse wave is employed for the impulse response analysis. The present analysis method is expected to be a useful method to plan and design for noise barrier or various construction works in urban area, and also help make a consensus between the constructor and the local residents.

1 INTRODUCTION

In our previous research [1], in order to perform sound field analysis efficiently, an impulse response analysis method based on wave acoustic theory using AMR (Adaptive Mesh Refinement) and CIP method and auralization system has been developed in order to perform sound field analysis efficiently. The method has only been assumed only complete reflection. However the real sound wave have attenuation with a reflection and a transmission by road surface or noise barrier effect. Since the noise prediction without any attenuation was low

accuracy, it can not be applied to the practical designing or planning. In order to improve the applicability of the method, the acoustic impedance which is the characteristic value of the medium acting as a resistance are considered. Reflection and transmission occur in the portion where the acoustic impedance extremely changes. The boundary condition with acoustic impedance was introduced into our analysis procedure. The following three assumptions are considered, (1) no dependence of reflection and transmission on frequencies, (2) no phase difference between reflected wave and transmitted wave, (3) no energy loss on the boundary. As the result of computational analysis, a method to express simply reflection and transmission phenomenon is proposed. This method is applied to a benchmark problem and the validity of its numerical result is examined by comparing with the theoretical solution. Also, effects of convolution and auralizatinon are investigated.

2. CIP METHOD

2.1 Governing equations and Characteristic curves

The one-dimensional wave propagation in the air can be expressed by the equation of motion and the equation of continuity as

$$\rho \frac{\partial u}{\partial t} + \frac{\partial p}{\partial x} = 0 \tag{1}$$

$$\frac{\partial p}{\partial t} + \rho c^2 \frac{\partial u}{\partial x} = 0 \tag{2}$$

where p [Pa] is the sound pressure, u [m/s] is the particle velocity, ρ [kg/m^2] is the density of air, and c [m/s] is the sound velocity. Equations (3) and (4) are obtained by multiplying equation (1) by c and adding to or subtracting from equation (2):

$$\frac{\partial}{\partial t} f_x^+ + c \frac{\partial}{\partial x} f_x^+ = 0 \tag{3}$$

$$\frac{\partial}{\partial t} f_x^- - c \frac{\partial}{\partial x} f_x^- = 0 \tag{4}$$

where f_x^+ is defined as $f_x^+ = \rho c u + p$, f_x^- is defined as $f_x^- = \rho c u - p$. Equation (3) and (4) represent the positive propagation of f_x^+ and the negative propagation of f_x^- by the speed c. The physical values at the next time step n+1 are obtained by advecting those values at the current time step n along the characteristic curves as shown in **Fig.1**. As a result, the sound

pressure p and the particle velocity u can be derived as follows

$$p = \frac{f_x^+ - f_x^-}{2} \tag{5}$$

$$u = \frac{f_x^+ + f_x^-}{2\rho c} \tag{6}$$

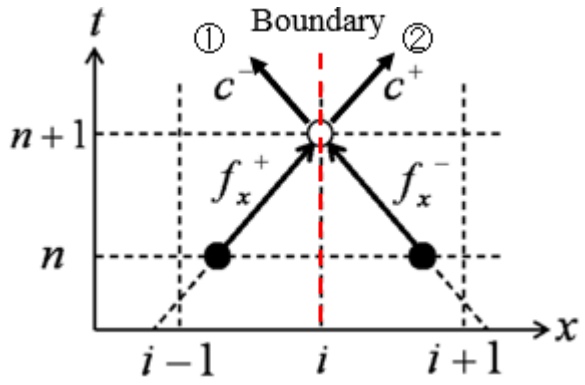

Fig.1 Advection on characteristic

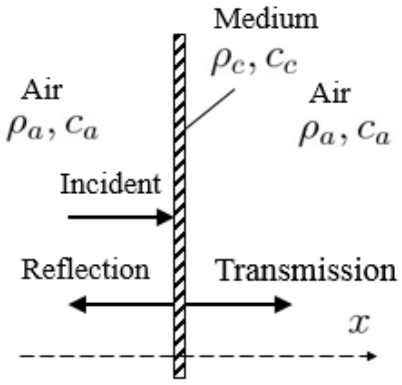

Fig.2 Reflection and transmission with acoustic impedance

2.2 CIP Interpolation

The CIP (Constrained Interpolation Profile) method [2] is a highly accurate differential solution method for advection equations that move physical quantities along characteristic curves. When obtaining the physical quantity to be advected, the CIP interpolation that interpolates from the physical quantity and the derivative value at the lattice point by using a cubic polynomial is performed, thereby the profile of the exact solution is relatively well maintained. The multidimensional problem extends the one-dimensional CIP method to each coordinate axis direction. In the case of three dimensions, it is obtained by solving advection equations for y direction and z direction in addition to equations (3) and (4). The CIP method realizing this multidimensional advection includes the M type CIP method and the C type CIP method. In this research, the C type CIP method which enables high accurate analysis is used [3].

2.3 Acoustic impedance

In this research, acoustic impedance is introduced to ensure the accuracy of the noise prediction result by considering attenuation due to reflection and transmission. The acoustic impedance is the characteristic value of the medium acting as a resistance. Reflection and transmission are generated in the portion where the acoustic impedance extremely changes as shown in **Fig.2**. The boundary condition considering the acoustic impedance is introduced. The following three assumptions are considered, (1) no dependence of reflection and transmission on frequencies, (2) no phase difference between reflected wave and transmitted wave, (3) no energy loss on the boundary. Then, the reflection and transmission phenomenon can be simply treated analysis method. The acoustic impedance on the boundary is expressed by the following formula.

$$Z_c = \rho_c c_c = -\frac{p_c}{u_c} \tag{7}$$

Z_c is the impedance, ρ_c is the density, c_c is the sound speed, p_c is the sound pressure, u_c is the particle velocity in the assumed boundary. Sound pressure and particle velocity according to (5), (6) are substituted to this equation on the boundary. Then the following formula is derived.

$$f_x^+ = \frac{Z_c - Z_a}{Z_c + Z_a} f_x^- \tag{8}$$

Z_a is impedance of the air. Similarly, regarding the transmission direction,

$$\frac{2Z_a}{Z_c + Z_a} f_x^+ \tag{9}$$

Then, assuming that there is no energy loss at the boundary, coefficients of the formulas (8) and (9) are determined so that the reflection and the transmission together become 1.

3. INCIDENT WAVE CONDITION USING IMPULSE RESPONSE

3.1 Impulse response

Impulse response is obtained at a sound receiving point when a very short wave signal is input to a certain space. By convolving the impulse response obtained by analyzing in advance and

the input waveform, it can be easily obtained the output waveform at the sound receiving point. When a sound data is used as an input wave , auralization can be realized.

3.2 Pseudo impulse

The Dirac delta function with a flat frequency characteristic is suitable for the impulse response analysis. However, since the real impulse has a steep shape, it is difficult to calculate with high accuracy using the discretization method. For this reason, a pseudo is approximate discretization is used. In this study, a pseudo impulse based on convolution integral method proposed by Lubich which is expressed by the following equation [4].

$$p_n \ \Delta t \quad \cong \ \frac{R^{-n}}{L} \sum_{L=0}^{L-1} \left(\frac{1}{4\pi r} e^{\frac{-sr}{c}} \right) e^{\left(-2\pi i \frac{nl}{L}\right)} \tag{10}$$

Fig.3 illustrates the waveform and frequency characteristic of Lubich pseudo impulse response with r = 0.2 m and Δt = 0.01026 ms in the equation (10). A constant spectrum up to 3500 Hz and a rapid decrease in higher frequency range can be seen in **Fig.3**.

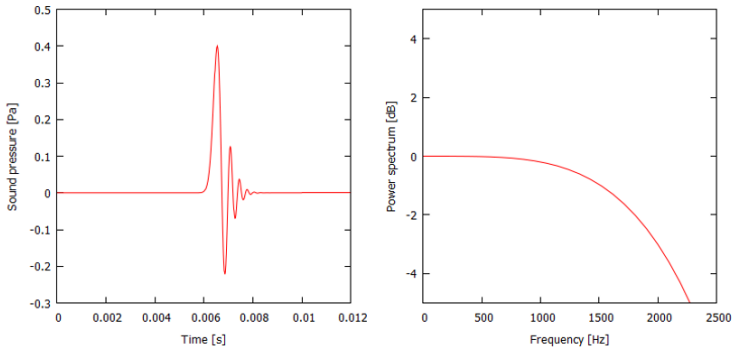

Fig.3 Waveform and frequency characteristic of Lubich pseudo impulse response

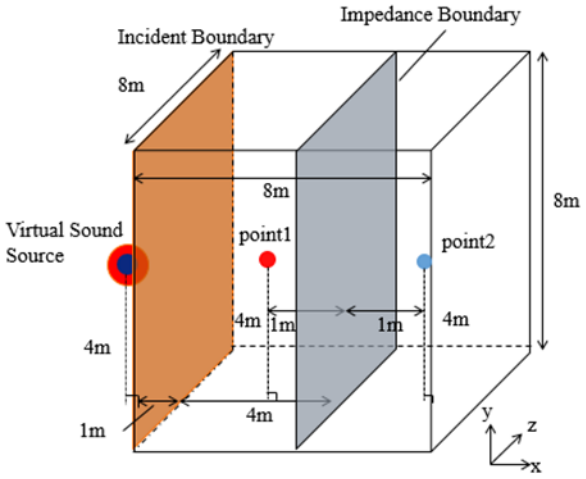

Fig.4 Computational domain (1)

4. NUMERICAL TEST EXAMPLE

4.1 Numerical Conditions

The computational domain is shown in **Fig.4**, and analysis with a minimum space discretization width of 0.015625 m and a time discretization width of 0.020525 ms (CFL = 0.45) was carried out. The distance between the virtual sound source and the incident boundary was set to 1 m, an impedance boundary was set at 4 m from the incident boundary, and sound receiving points were set 1 m front and 1 m backward from the impedance boundary (1 m front: point1 , 1 m backward: point2) [5]. Z_c= 1224 Pa · s / m and Z_a = 408 Pa · s / m were set as values of acoustic impedance. Z_c is a virtual acoustic impedance and is set to a value such that the sound pressure peak theoretically becomes 0.5 times as compared with the perfect reflection or complete transmission. Acoustic impedance Z_c = 1224 Pa· s / m, Z_c = ∞ Pa· s / m, and Z_c = 408 Pa· s / m correspond to case1, case2 (perfect reflection) and case3 (perfect transmission), respectively.

4.2 Numerical Results

Fig. shows the sound pressure distribution and mesh idealization for each case in x-y section (z axis is 4 m height). **Fig.** shows the time history of sound pressure at receiving points. At point1, the primary wave is a direct wave and the secondary wave is a reflected wave. The solid line is the case1, the dotted line is the case2 analysis result. From **Tab.1**, the peak ratio of sound pressures is close to 0.5, which is in a good agreement with the theoretical value .

Similarly, the time history of sound pressure at point2 is shown on **Fig.** . When the solid line is the case1, the dotted line is the case3 analysis result. From **Tab.2**, the peak ratio of these sound pressures is also close to the theoretical value.

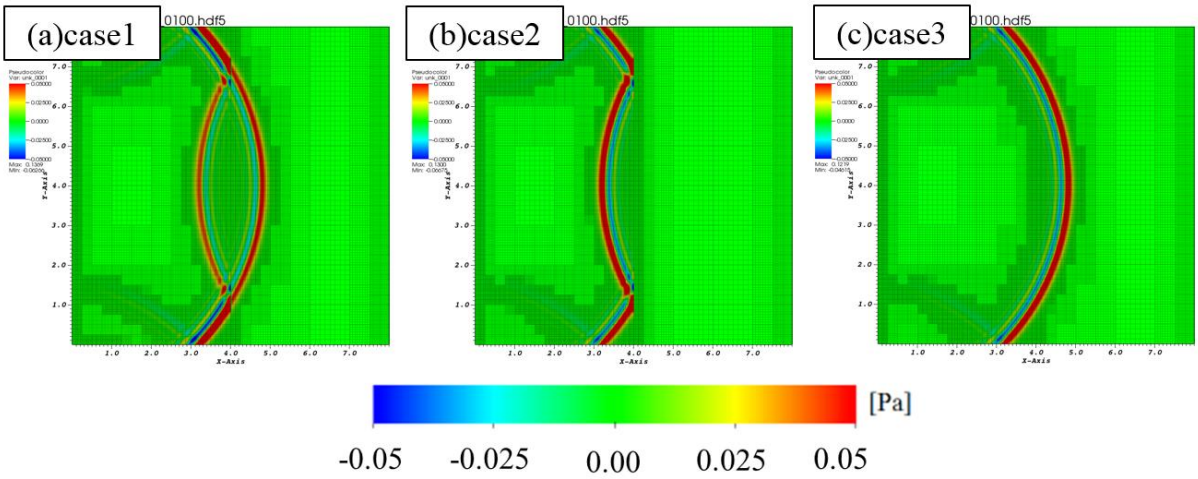

Fig. Sound pressure distribution and mesh idealization for each case

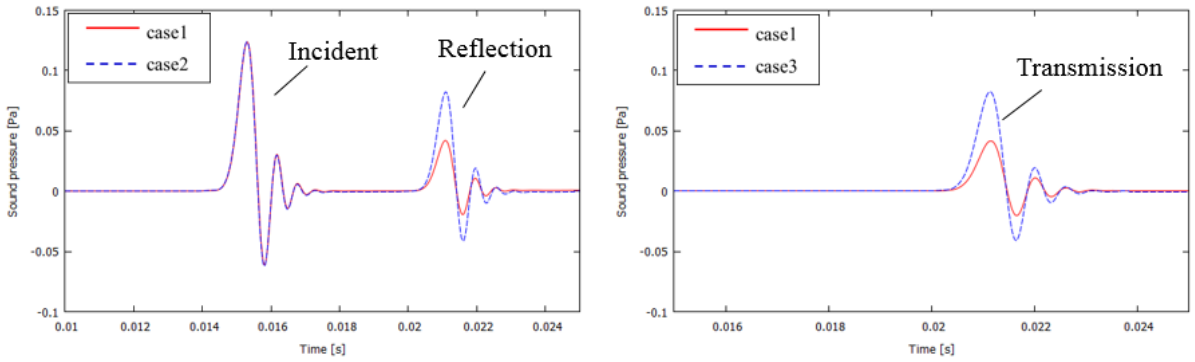

Fig. The time history : point1 (left) and point2 (right)

Tab.1 Comparison of peak values at point1

	case 1	case2	Ratio
point1	0.04198	0.08222	0.51

Tab.2 Comparison of peak values at point2

	case 1	case3	Ratio
point2	0.04173	0.08246	0.51

5. AURALIZATION EXAMPLE

Auralization is realized by converting the output result (numerical data) obtained at the sound receiving point to sound WAV data. The converted WAV data is auralized using a speaker in the VR device. In our previous research, a system that can simultaneously provide the visual information and auditory information was developed [6]. In this system, a stereophonic sound presentation method based on Ambisonics is adopted [7].

The auralization setting is shown in **Fig.** . The analysis conditions are the same as the example in section 4. The distance between the virtual sound source and the incident boundary was set to 1 m, impedance boundary (noise barrier) was set at 4 m from the incident boundary, the barrier is 4m height, and sound receiving points were set 1 m backward from the impedance boundary.

The convolution results of sound source data and impulse response in each case are shown in **Fig.** . Breaking noise is adopted as sound data for convolution. As a result, the sound pressure lowering can be confirmed by considering the acoustic impedance. **Fig.** shows the state of projection by VR device. The actual auralization sound will be indicated at the presentation.

Fig. Convolution results for each cases

Fig. Projection by VR device

6. CONCLUSION

In this research, this method has been applied to the benchmark problem and the validity of its numerical result has been examined by the comparison with the theoretical solution. The conclusions are as follows:

・By considering the acoustic impedance, the sound pressure peak ratio of simulated result to both perfect reflection and complete transmission showed good agreement with the theoretical value. As the results, the usefulness of the presented analysis method could be confirmed.

・In the auralization examination, the attenuation of the sound waveform could be well expressed.

In the future work, this method will be applied to models assuming actual noise barrier and residential environment.

Macro-element Strategy Based upon Spectral Finite Elements for Transient Wave Propagation. Application to Ultrasonic Inspection of Composite Structures

Alexandre Imperiale*, Edouard Demaldent**

*CEA LIST, **CEA LIST

ABSTRACT

Modelling high-frequency wave propagation is a major asset in numerous advanced industrial fields. However, proposing a numerical solution of these problems require complex and expensive computational procedures. Furthermore, it is often expected from numerical solvers to support parametric variations, imposing efficient management of batches of configurations. In order to address both difficulties, we propose a modelling strategy relying on a reciprocity relation [1] based upon the distinction of incident and diffracted fields. This separation enables to isolate the varying part of the configurations in a localized area, so that the overall computational load is significantly reduced. Concerning the numerical solver itself, we propose a numerical computation strategy based on a domain decomposition approach. The topology of each subdomain is obtained from the deformation of a reference hexahedron, thus allowing the construction of a dedicated mesh data structure supporting high-order finite element spaces [2] and leading to optimized unassembled finite element operations. Upon the assumption of conform interfaces, the transmission between theses macro-elements can been carried out naturally by gathering contributions at interfaces, or in more complex cases, e.g. fluid-structure interactions, using the mortar element method [3]. We apply this approach to ultrasonic inspections of 3D plate-like carbon fiber reinforced composite structures. In this context, traditional homogenization procedures lead to stratified anisotropic material properties, whose anisotropic orientations depend on the geometric deformation of the specimen (e.g. from flat to curved media). To that end, we introduce two coordinate systems representing the specimen prior to and after its deformation, and passing from one system to another enables on-the-fly reconstruction of local fiber orientation. Splitting directions typically used in absorbing layer formulations are deduced in the same manner. [1] B. A. Auld. Optimal Design of Thermoplastic Composite Quilted Stratum Process Manufactured Parts

Francois-xavier Irisarri*, Cédric Julien**, Terence Macquart***, Denis Espinassou****

*ONERA, Châtillon, France, **ONERA, Châtillon, France, ***University of Bristol, United Kingdom, ****CETIM, Nantes, France

ABSTRACT

A novel framework for the optimization of composite structures manufactured using the recently developed Quilted Stratum Process (QSP®) is presented in this paper. Over the last decades, the excellent mechanical properties of composites over their metallic counterpart have resulted in the growing use of composite materials in aerospace industries. However, applications to other industries have been limited due to their higher costs and long processing times. The QSP® consists in the stamping of an assembly of thermoplastic composite patches having unidirectional or woven reinforcement. As such, QSP® is suitable for the cost-effective and automated high speed production of composite parts. It encompasses the continuous production of composite bands as well as its automated cutting, positioning and stamping. Despite the potential cost and time benefits associated with this new manufacturing process, there is currently no method available for the design of composite parts associated with QSP®. In this research, we develop the first design and optimization method adapted to the composite parts manufactured by QSP®: the so-called Quilted Stratum Design (QSD®). QSD® is based on a two-level optimization strategy. At the first level, a continuous structural optimization problem is solved using lamination parameters as design variables. The optimal solution obtained gives an idealized target defining the best achievable mechanical performances and the corresponding stiffness and thickness distributions over the structure. The second optimization step aims at retrieving a manufacturable structure that matches the target solution. A typical QSP® part is built from a net-shape preform, which is assembled from patches of different size, thickness and material. Thus, in the present work, the QSP® part is encoded using two sets of indices. The first one refers to a user-defined material library while the second one refers to a library of available patches. This patch library is determined based on the clustering of the target stiffness and thickness distributions in order to bring out areas of uniform stiffness properties and thickness. Consequently, a patch is defined as a shape, size and position on the flattened form of the part. Furthermore, in order to minimize the material waste and cost, patch shapes are restricted to trapezoids cut in the full width of a band. Hence, the basis of the trapezoid defines the material orientation of the patch. This description of the QSP® part lends itself nicely to be implemented in an evolutionary optimizer, which is thus used to solve this second optimization step.

Simulating Traffic Congestions in a City after a Major Earthquake Using a Large Number of Demand Patterns

Takamasa Iryo*, Junji Urata**, Kazuki Fukuda***, Riki Kawase****, Genaro Peque Jr.*****, Lalith Wijerathne******, Wasuwat Petprakob*******

ABSTRACT

A road network is likely to be severely congested after a major earthquake. Damages on infrastructure and buildings significantly reduces capacity of a road network. The deterioration of a road transport system will delay a lot of travels including essential ones such as rescues of victims and interfere a recovery from a disaster. Assessing congestion of a road network in a recovery process from a disaster is essential to maintain disaster resilience of a city and country. Simulating a traffic flow by a computer is a popular approach to assess road congestion. However, existing ones basically intend to simulate a normal situation with a fixed traffic demand pattern given. Estimating a single demand pattern after a major earthquake before it happens is virtually impossible. We construct a stochastic model describing how the demand is generated. Then, various demand patterns that are likely to happen are sampled by a Monte Carlo simulation. A large number of demand patterns generated by the stochastic model should be similar to each other. This property would be useful to reduce total calculation time of simulations for all demand patterns. However, this is not a trivial task owing to the time-dependency of traffic congestions. We developed an efficient algorithm for different demand patterns that are similar to each other by HPC (high-performance computer). In the algorithm, a traffic flow is regarded as a continuous flow like a fluid flow. Dynamics of a traffic flow is described by a partial differential equation system called LWR (Lighthill-Whitham-Richards) model. A traffic flow patter of each link is independently calculated by the LWR model. To parallelise the calculation, a road network is divided into a number of sub-networks and they are assigned to each CPU. Inconsistency of traffic flow patterns between links are likely to happen owing to the calculations ignoring interdependency of a traffic flow across links. This inconsistency is corrected by repeating the process that transmits information of traffic flow patterns between links and updates a traffic flow pattern in each link. The traffic simulator is designed to handle a network of Tokyo and surrounding area in Japan including about 400 thousand links and 26 million vehicle trips. In the session, we present case studies of thus network, as well as details of the simulation.

Phase-field Simulation of Diffusional-displacive Transformation and Stress-strain Response in Ti-Nb-O Alloys

Yuya Ishiguro*, Yuhki Tsukada**, Toshiyuki Koyama***

*Nagoya University, **Nagoya University, ***Nagoya University

ABSTRACT

Beta-type Ti-Nb alloys exhibit shape memory and superelasticity properties due to the martensitic transformation (MT) from beta phase (parent phase) to alpha" phase (martensite phase) and are assumed to be promising materials for biomedical applications [1]. When oxygen is added to Ti-Nb alloys, the stress-strain hysteresis of the alloys becomes slim as the oxygen content increases. This unique property has been considered to be related to the nanoscale minute martensite, which is called nanodomain [2]. In this study, we focus on the spinodal decomposition of beta phase at 1073 K and its effect on the stress-strain response at room temperature. The spinodal decomposition of beta phase in Ti-Nb-O alloys was simulated by the phase-field method using thermodynamic parameters of equilibrium phase diagram. Simulation results show that the oxygen addition induces the spinodal decomposition, and the beta phase separates into nanoscale beta1 and beta2 phases; the beta1 is O-rich, Ti-rich and Nb-lean phase and the beta2 is Nb-rich, O-lean and Ti-lean phase. Thermodynamic analyses have revealed that the increase in oxygen content in Ti-Nb-O alloys increases the driving force for the spinodal decomposition. The external tensile stress was applied to the calculated (beta1 + beta2) microstructure to simulate the MT and the stress-strain response at room temperature. It has been shown that the beta1 phase preferentially transforms to the alpha" phase when the external stress exceeds a critical value but the beta2 phase acts as a local barrier against the MT. As a result, the long-range MT is suppressed and the minute alpha" phase is formed reflecting the nanoscale beta1 phase. However, the beta2 phase also transforms into the alpha" phase when the magnitude of external stress is increased. The Gibbs free energy calculation has revealed that the difference of the driving force for the MT (Gibbs free energy difference between the beta and alpha" phases) between the beta1 and beta2 phases is attributable to the niobium concentration difference between the two phases. It is assumed that the formation of nanodomain and the unique stress-strain response in oxygen added Ti-Nb alloys are closely related to the nanoscale heterogeneity of the niobium concentration derived from the oxygen induced spinodal decomposition at high temperatures. ABSTRACT

Carbon capture, utilization, and storage (CCUS) describes a set of technically viable processes to separate carbon dioxide (CO2) from industrial byproduct streams and inject it into deep geologic formations to store it from the atmosphere and/or improve hydrocarbon recovery. Behavior of such engineered geologic systems is complex, and involves coupled interactions of various natural and man-made components that can significantly impact system performance. Legacy wells located within the spatial domain of new injection and production activities represent potential pathways for unwanted fluid migration, and understanding their response to those activities is needed to ensure hydrodynamic isolation of targeted intervals. Finite element (FE) method numerical techniques represent a useful tool to simulate those multi-phase and multi-component interactions. The potential presence of cracks in the cemented well annulus can open a pathway to allow unwanted vertical migration of fluid (i.e., CO2 , and aqueous-phase) and create conditions for further crack propagation due to hydraulically induced stresses. In this study, a single-casing composite well system is considered, composed of steel casing, cemented annulus, and rock formation with a partial microannulus formed at the interface of the steel casing and the cement sheath. Using an open-source code [1], a coupled FE analysis is conducted. The flow is assumed to be isothermal and the effects of temperature are ignored. To account for the flow of CO2 phase and the aqueous phase, a two-phase flow [2] approach is applied in to describe flow and stress response in the interfacial crack. Furthermore, the porous solid media (cement and rock) are modeled using the elastic-plastic Mohr-Coulomb criterion. The solid steel is modeled as a linear elastic material. To illustrate the gas-phase and liquid-phase transition, the van Genuchten model [3] is used. In this paper, the effects of interfacial crack width and length on the predicted mechanical stress distribution and fluid flow are investigated. References: [1] Kolditz, O., et al. (2012). Progressive Collapse Analysis of Buildings and Its Risk Estimation Using Key Element Index

Daigoro Isobe*, Kota Azuma**

*University of Tsukuba, **University of Tsukuba

ABSTRACT

In case of emergency such as intense fire or collision of some objects to buildings, there is a risk of progressive collapse; a phenomenon which occurred to the World Trade Center (WTC) towers during the 9.11 terrorist attacks. The official statements released by the Federal Emergency Management Agency (FEMA) in 2002, and also by the National Institute of Standards and Technology (NIST) in 2005 and 2008, concluded that the details of the failure process after the decisive initial trigger that sets the upper part in motion were very complicated and their clarification would require large computer simulations. In this study, the collapse behaviors of steel framed buildings are simulated using the Adaptively Shifted Integration (ASI) - Gauss code to investigate the relation between a key element index, which indicates the contribution of a structural column to the vertical capacity of the structure, and the scale of progressive collapse. Collapse was initiated by removing specific columns from the models designed based upon different axial force ratios. Some patterns of removed columns, of which the locations were restricted to a single floor, were investigated. The total potential energy values of structural members after the collapse were used to estimate the collapse scale of the buildings. By evaluating the numerical results using the key element index, it was found that the larger the integrated value of key element index the higher the risk of progressive collapse; however, some peculiar tendencies were observed in the cases of removed columns with extremely symmetrical or asymmetrical locations. The critical integrated values of key element index to cause a large-scale progressive collapse tend to depend on the strengths of buildings, and they cannot be uniquely decided. This is due to the fact that the key element index is a parameter which does not relate to the strength of the building itself, and it cannot be compared relatively between buildings with different strengths. Therefore, the key element index may be used to predict and compare the risks of progressive collapse, only in the same building, but even when the locations of removed columns are variously assumed. Numerical Simulation of Electro-Thermal Ice Protection Systems

Emiliano Iuliano*, Michele Ferraiuolo**

*CIRA, the Italian Aerospace Research Center, **CIRA, the Italian Aerospace Research Center

ABSTRACT

Aircraft in-flight icing represents a major threat for aviation safety. Along the flight path, an aircraft component may encounter a cloud with super-cooled water droplets that, due to their unstable status, may freeze upon impact. The formation of a thin layer of ice can significantly alter the aerodynamic performance, thus leading to drag increase, lift reduction, loss of control, engine flow distortion and compressor blades structural damage (if ice blocks are ingested within the engine inlet). In order to avoid such issues, ice protection systems are usually installed on critical components like wings, tails, probes, engines. These systems can be classified into de-icing and anti-icing systems. The former aims at breaking the bond of already formed ice with the solid substrate (expulsive or heated types); the latter, instead, are activated prior or during the icing process to prevent any ice formation (heated types, coatings). With reference to anti-icing, the focus of the present investigation is on electro-thermal systems. In this case, the solid substrate consists of a multi-layered structure with heater elements (resistors) embedded at interfaces between layers. The aim is to increase the surface temperature above the freezing point, allowing the caught water mass to flow downstream (running-wet anti-icing) or to evaporate (evaporative anti-icing). The role of numerical simulation is crucial in designing such systems and in reducing the experimental testing burden. The current practice is to size it by evaluating the most critical icing conditions through ice accretion simulation, identifying the regions where ice is expected to grow and, finally, estimating the heating power. Here, a coupled methodology to simulate and optimize the performance of an electro-thermal anti-icing system is proposed in an integrated fashion. The classical tool chain of icing simulation (aerodynamics, water catch and impact, mass and energy surface balance) is coupled to the heat conduction analysis through the multi-layered substrate. Steady and unsteady coupling approaches have been implemented: the first is computationally lighter while the latter is mandatory when heaters are switched on with predefined temporal laws. A thorough comparison between the two methods will be shown. Validation results obtained on benchmark test cases, drawn from NASA database, will be detailed as well as comparison with numerical results from literature.

A Moment Method for Polydisperse Flows Resulting from a Radiological Dispersal Device

Lucian Ivan*, Francois Forgues**, James McDonald***

*Canadian Nuclear Laboratories, **University of Ottawa, ***University of Ottawa

ABSTRACT

Accurate prediction of the dispersal of particles resulting from the detonation of a radiological dispersal device (RDD) presents many modelling and numerical challenges, especially when urban environments are considered. Certain modelling challenges occur due to the presence of a range of particle sizes generated in the fragmentation process and the associated fireball. Furthermore, radioactive particles in such flow situations transition from a granular-phase regime near the explosion site to a dilute-phase farther away. The particulate phase at locations within each regime will likely display a range of velocities and particle sizes. This talk presents a moment model designed to accurately treat these effects while remaining computationally affordable for large-scale practical calculations. The proposed model is an extension of the well-known maximum-entropy ten-moment model from rarefied gas dynamics with an addition for the treatment of a range of particle diameters. This model allows for anisotropic variance of particle velocities in the phase space and directly treats correlations between particle diameter and velocity. The resulting system comprises fifteen first-order hyperbolic balance laws that are quite simple mathematically. For example, the flux Jacobian possesses an eigenstructure that can be expressed entirely in closed form, and consequently, it allows in-depth analysis of the system's behaviour. This talk presents a derivation of the model and an analysis of the eigenstructure of the system, which characterizes the fifteen waves that are present. For simple diameter-dependent particle-drag models, such as Stokes flow, a dispersion analysis is presented that quantifies the behaviour of the model from the free-flight, drag-free regime all the way to low-Stokes-number, drag-dominated flows. This demonstrates the stability of the partial differential equations describing the model and shows how the apparent waves, present in solutions, are affected by the regime in which a flow exists. A numerical implementation for one- and two-dimensional problems is presented. Numerical solutions for simple problems, for which analytic solutions are available, as well as large-scale computations that are more typical of real-world situations are shown to illustrate the predictive capabilities of the model. It is shown that the new model offers clear advantages in terms of accuracy when compared to traditional Eulerian models for multi-phase flows.

Topology Optimization of Nonlinear Periodic Microstructures with Viscoplastic Material Properties

Niklas Ivarsson*, Daniel Tortorelli**, Mathias Wallin***

*Lund University, **Lawrence Livermore National Laboratory, ***Lund University

ABSTRACT

In this talk we discuss a framework for generating optimal topologies of periodic microstructures with viscoplastic constitutive behavior. Finite deformation is considered and materials with tailored macroscopic mechanical properties are designed. We evaluate effective material properties by performing numerical tensile and shear deformation tests of a single unit cell, as opposed to standard homogenization approaches, and also incorporate irreversible material effects. The constitutive model that we employ was proposed by [1] and is based on finite strain isotropic hardening viscoplasticity. The mechanical balance laws are formulated in a total Lagrangian setting and solved using the Newton-Raphson algorithm together with an adaptive time-stepping scheme. The optimization problem is regularized by introducing a periodic version of the Helmholtz' partial differential equation filter and iteratively solved using the method of moving asymptotes (MMA) which is based on the gradients of the cost and constraint functions. Since the material model is path-dependent the sensitivity will be so too. Sensitivities needed for each design update are obtained from the adjoint sensitivity scheme presented in [2] which for plasticity will be a terminal value problem. In the numerical examples we consider several objectives: 1) tailored specific stress-strain response, achieved by minimizing the error between actual end prescribed target response, 2) design of microstructures for maximum energy dissipation. Near black and white solutions are obtained through the use of Heaviside thresholding technique and penalization of intermediate designs. The applicability of the algorithm is demonstrated by several numerical examples of optimized three-dimensional plane strain continuum structures exposed to multiple load cases over a wide macroscopic strain range. This work was partially performed under the auspices of the U.S. Department of Energy by Lawrence Livermore Laboratory under contract DE-AC52-07NA27344, cf. ref number LLNL-CONF-717640. Masonry Micromodels Using High Order 3D Elements

Salvador Ivorra*, J.I. Gisbert**, D. Bru***, F.J. Baeza****

*University of Alicante, **University of Alicante, ***University of Alicante, ****University of Alicante

ABSTRACT

The main objective of this paper is the use of high order 3D elements in the numerical modelling of masonry structures. For this purpose, FE models corresponding to standard tests were made and calibrated using results of experimental tests. In particular, this document will analyze the resistant behavior to uniaxial and diagonal compression walls made with brick. The numerical micromodel has been developed using the ANSYS code with non-linear hexaedrical 8 and 20 nodes tridimensional elements to represent brick and mortar, such as solid185 and solid186, in contrast to traditional FE models which use element solid65 as finite element to represent masonry behavior. Drucker-Prager and Rankine models have been used to study the compression-tension failure surface, adding a linear hardening-softening-dilatation behavior. Moreover, fracture-energies based cohesive zones have been added to contacts between mortar and bricks, in order to allow debonding failure between these two materials. These modelling method prove to be a valid technique to simulate brick masonry behavior according to experimental results, and will be used as a base to develop FEM analysis to study the effect of Textile Reinforced Mortars (TRM) to reinforce masonry specimens.

PRACTICAL STEPS TOWARDS PERFORMANCE STEWARDSHIP FOR COMPUTATIONAL SCIENTISTS

C. Iwainsky, and D.C. Sternel

Hessisches Kompetenzzentrum für Hochleistungsrechnen[1]
Technische Universität Darmstadt
Alexanderstraße 2, 64289 Darmstadt, Germany
e-mail: [iwainsky,sternel]@hpc-hessen.de;
web page: http://www.hkhlr.de/

Key words: Performance Engineering, Active Performance Documentation, Performance Stewardship

Abstract. Achieving high performance has been in the focus in the past, but sustaining achieved performance remains an open topic. Performance degradation, if not actively monitored for, can creep in and severely diminish the productivity of codes and their operating scientists' research. The current state of the art to detect such a creeping performance loss is performance analysis. A performance analysis is a considerable investment in resources to generate the necessary data and to subsequently analyze it. The resulting insight is only directly applicable to the specific analyzed software variant and data set. Each code variant and configurations must be, in principle, separately analyzed to ensure the absence of performance bugs. Therefore, frequently repeated performance analysis is not sustainable for every program execution during the long lifespan of a code. We present, how so called "active performance documentation" can be used to achieve resilience against performance loss from creeping code deterioration or configuration errors. Such an active documentation consists of small code augmentations placed at critical points in the program that monitor specific performance indicators, and validate those against specifications of acceptable performance. Thus, developers and users of a code using active performance documentation will be aware, when and if the performance of their code deteriorates, at which point appropriate counter-measures can be undertaken. With the use of active performance documentation, users and developers of computational code will be able to react to performance problems, instead of having to proactively scan for potential issues.

[1]The "Hessisches Kompetenzzentrum für Hochleistungsrechnen"' is funded by the Hessian State Ministry of Higher Education, Research and the Arts.

1 Introduction

Performance is an important aspect of many scientific applications, as computational solutions require typically a large invest of High Performance Computing (HPC) resources. Here, performance is defined as the ability to utilize a given amount of computational resources to produce as much meaningful work as possible. While achieving performance has been in the focus in the past, resulting in a plethora of technological and methodological techniques, the issue of sustaining performance achieved remains an open topic.

The performance is limited by the constraints of the specific hardware used and by the capability of the used software to make efficient use of these resources. Examples for hardware constraints are network performance, CPU performance, available memory, storage performance, or the maximum up-time of a system; examples for software constraints are the data-set size or the precision required of the result. A good performance is all too often a trade-off between user-requirements and available resources. To preserve good long term performance, an achieved performance must be monitored and maintained to account for changes in constraints and requirements.

While changes in hardware are rare and obvious, changes in the software or its runtime configuration and their effects are subtle and frequently remain unnoticed. This is especially the case in an academic environment, where software is actively worked on to keep up with advances in domain knowledge and methodology or applied to substantially different scenarios than it was originally intended for. This, in combination with the loss of usage-experience due to frequently changing developer and user base caused by academic life-cycles and project driven development, creates an environment where the performance of a software can decrease without being noticed, if not actively monitored for.

Performance Stewardship (PS) describes the holistic approach where the performance of a software is not a simple byproduct, but a primary concern on the same level as software features or correctness. It follows, that the performance of a software is something to be actively preserved and maintained in all phases of its life-cycle. One important aspect of PS is the monitoring of program executions and evaluation of the resulting information to detect degrading performance. The current state of the art relies entirely on the user to use performance models or to conduct a performance analysis:

1. Performance models parameterized by the software configuration traits and hardware parameters are used to predict values of observable metrics, such as the walltime of the application. If the observed metric matches with the predicted value, then the performance is considered to be OK, and if not, a performance problem must have occurred.

2. For performance analysis, dedicated measurement runs are used to generate performance data that is analyzed for performance deficiencies. This analysis is substantially based on experience of the analyst and uses usually an implicit and abstract performance model of the machine used and software executed.

Both techniques have their challenges. The precise performance models with predictive qualities required for the first approach are rare, and the creation of such models requires substantial expertise and considerable effort. Current research, such as the ExtraP-project [2], aims to make performance models more accessible, but still requires considerable expertise to use. The performance analysis approach is expert driven and resource-intensive in nature, as separate experiments must be conducted for the sole purpose of generating measurement data. Additionally, the measurement overheads incurred with current methods require a tailored measurement setup [4], which is configuration specific and often a result of multiple refinements of the measurement infrastructure. While performance analysis may lead to considerable insight in an applications runtime behavior, it is unfeasible to perform an user-driven analysis for every execution as the overheads of such an approach, be it runtime overheads or human time invested, would in most cases surpass the potential benefits in detecting performance creep.

Therefore, a more accessible method is necessary that can be used easily by developers and domain scientists to achieve performance stewardship of their codes.

2 Performance Mistakes

From years of experience advising and supporting users of different HPC systems[2], we identified three reoccurring performance issues: load balancing, over-parallelization and performance critical component misconceptions.

Load balancing, or the issue of unbalanced workloads, is a considerable challenge for scientific applications, both for multi-processing and multi-threading [3]. Simply stated, the principal issue is that, due to synchronization of imbalanced workloads, not all computational entities contribute evenly to the outcome. In consequence, some of the allocated resources are wasted and the performance of the program decreases. The underlying root-cause is case specific. Examples are imbalanced domain partitioning or software with adaptive refinement. Also external sources, such as intermittent network congestion or temperature based CPU over- or under-clocking, will effect the work balance of a parallel application. While users and developers are, in principle, aware of the work-balancing issue, countermeasures are challenging in both implementation and usage. On the one hand, runtime load-balancing methods are difficult to implement, incur additional overhead and are often not available in existing code-bases. On the other hand, static work-balancing, i.e. balancing the workload before each execution, requires prior information, a very good understanding of the input parameter and knowledge of resulting runtime behavior such as a performance model. For this reason, in everyday HPC usage, application users are rarely aware of their codes actual workload distribution.

Runtime **over-parallelization** is yet an other issue that users often struggle with. Over-parallelization describes the effect that with increasing parallelism the performance

[2]The authors currently support HPC users from all Hessian universities, such as user of the Lichtenberg HPC system at TU Darmstadt.

gains drop, to the point, where an additional degree of parallelism actually increases the runtime. Possible root causes are, for example, increasing communication-costs, as observed in previous work [5], or domain partitioning to the point at which each parallel entity has only a few elements to process; this can even culminate in each parallel entity having only a single element to process.

The following case study exemplifies this issue: A given code was used for parameter studies for material structure calculations, with hundreds of experiments to be conducted. The code was benchmarked by the user to assess its fastest configuration, which was determined to be at 72 MPI processes on three 24 core machines. However, the user did not realize that even though there was a continued speedup up to 72 processes, the efficiency had substantially dropped. In this case, the efficiency dropped from above 69.9% at 16 processes, to 35% at 32 cores down to 25% efficiency at 72 cores. As many of the planned experiments were independent from each other, the best performance for the user was to run 3 experiments at 16 cores, instead of one experiment at 72 cores. This provided a net-speedup for the desired work of 3x without any code modification. Had a mechanisms been available in the code to notify the user of a low efficiency, this situation would have been rectified much earlier than it was.

Performance critical component misconceptions (PCCM) is a collective term for performance issues originating from development practice. A PCCM is a performance issue caused by a code region or kernel that is considered by the developers of the code to be non-critical or where the developer is unaware of its existence. The problem of such a misconception is, that without explicit profiling, such expensive code regions are likely to remain unnoticed and therefore never addressed in tuning and optimization. The reasons for such PCCM are manifold.

For example, developers of parallel software aim to optimize their codes, but due to time constraints focus on perceived performance critical components and ignore less critical components. This is even further emphasized by the fact, that their intent is to implement new mathematical solvers or physical simulation capabilities to their code. Understandably, their development effort is spent to optimizing these regions. While focusing on critical code is important for good performance, it is easy to neglect tuning and optimizing the other aspects of a code, such as the I/O components before and after the computation intensive regions, or the management routines used for check-pointing or data-structure management. Such a PCCM, for example, was discovered by Calotoiu et al.[2] in a widely used weather simulation package, where an I/O related section had a so far unknown performance issue.

An other example for PCCM can be observed in codes with continued development. Here, the addition of new functionality, restructuring of code or inclusion of new methods can easily shift the location of computation heavy aspects. This, by itself, is not an issue, but optimizations made for the previous code version might no longer apply. Also a human element plays a problematic role: past experience with the code is frequently used without checking its validity for the new code version, thus creating possibilities for

PCCM and in conclusion to performance problems

Simple profiling, and other performance analysis methods, can and will detect such changes and shifts in performance critical regions and prevent PCCM. However, this requires the users and developers to use such tools in their daily development process. And even if such methods are known, the fact that such analyzes require explicit and additional after-development steps results in developers often simply neglecting this crucial step, as their actual goal is to conduct their computational experiments.

These three issues are a tiny sub-set of all potential performance issues. The three described, however, occur easily by mistake, even by experts, and are, in our experience, not too uncommon in the bulk of engineering applications run in HPC centers. Measurements of codes with production configurations are the only way to guard against such mistakes. The likeliness of such mistakes is unfortunately further amplified by the proliferation of ready-to-use packages, such as OpenFOAM, Wien2K or VASP, as a larger experience and knowledge gap exists between the original developers, who are typically aware of these issues, and "end-users" that have to learn to use the software as well as cope with all the peculiarities of good performance.

3 Active Performance Documentation

HPC users and code developers require an approach to automate the monitoring and analysis aspects, and the means to integrate this in their applications in order to mitigate the performance mistakes described earlier.

3.1 Method

To provide a practical mechanism in support of PS, we proposes the following approach:

- In a first step, the application is augmented with permanent measurement and analysis facilities in combination with developer defined performance criteria. Ideally the performance checks and validation are integrated directly into the code-base itself, but also external specifications and measurement facilities are possible.

- The resulting software is then used as is, allowing for unchanged application workflows without the need of interleaved explicit profiling and validation runs. As the added measurement and analysis system evaluates every execution, a creeping or accidental performance loss can not remain unnoticed and appropriate countermeasures can be applied.

We call this concept *active performance documentation* (APD), as the mechanisms in the code document the expected performance behaviour.

Such APDs provide, on the one hand, a confidence and ease of mind into the scientific software, as it will "notify" the user when the software is running deficient. Also, performance experts, such as members of the many performance engineering groups at HPC centers, can focus their effort on known deficient codes, instead of having to proactively

triage all codes for their performance. On the other hand, the run-time measurement and validation of complex performance models will add overhead, which must be controlled for.

3.2 Performance Model Simplifications

Active performance documentation is at its core a hybrid of both performance models and measurement-based performance analysis. It therefore requires aspects from both methods: a sufficiently precise performance model, which is, as described earlier, difficult to come by, and a low-overhead measurement system, which is also challenging to integrate into arbitrary codes. This would be too complex for most domain experts and engineers to apply to their codes. Fortunately, for the three specific performance mistakes described earlier, i.e. load-imbalances, over-parallelization and performance critical component misconceptions, simplifications can be applied that eliminate the need for an explicit mathematical performance model[3] and that have, in comparison, lower and easier controlled measurement costs.

To derive these simplifications, we first define the performance issues and demonstrate how the complexity of performance models can be substituted by far more easily implemented runtime measurements:

A load imbalance is defined as follows: Assuming that the target metric is the runtime $\mathbf{t}$ and the (performance) model $\mathcal{T}(\mathbf{R}, ...)$ describes the runtime of a parallel computing entity[4] P_n for a specific region $\mathbf{R}$ of code, then a load imbalance is defined by $\mathcal{T}(P_a, \mathbf{R}, ...) < \mathcal{T}(P_b, \mathbf{R}, ...)$. The ellipsis here is a placeholder for the many additional arguments required, such as machine specific parameters like memory bandwidth or networking latency, and input parameters like the domain size used. To assess, if this comparison is true for a given program for all configurations, a performance model replicate all aspects of the code, which is very complex. However, as active performance documentations do not intend to argue this equation for all executions, but only for a specific execution, the model of a specific region can be substituted by a runtime measurement. Therefore, it is not necessary compute the runtime of the different computation entities from parameters, but the desired metric, i.e. runtime, can be simply measured, communicated and compared on a global level.

Similarly, for over-parallelization, the local workload can be compared to the various overheads. Here, performance models, (see [1]), describe the time spent in the CPU and other components as sums of partial models, each modeling specific aspects of the program, such as communication, I/O and other activities. To ensure that a specific component, such as the computation, remains the dominant part, the individual terms of the model can be separated and compared to each other. Assuming that the runtime model $\mathcal{T}$ can be split into the component models for CPU time $\mathcal{T}_{\text{cpu}}(\mathbf{R}, ...)$ and commu-

[3] An example and its derivation for such a model can be found in Bauer et al.[1].

[4] A parallel computing entity can be a process or thread, with the number n used as means for identification.

```
1 for (time_step < end) {
2         while(not_converged) {
3                 exchange_local_boundaries(...);
4                 compute_local_solution(..);
5                 communication_error(...);
6         }
7   compute_global_contribution(...);
8   communicate_global_contribution(...);
9 }
```

Listing 1: Demonstrator Pseudocode

This pseudo-code mimics the a compute and communication structure found in some fluid dynamics codes. Compute only regions are highlighted in green color, and communication and synchronization in red color.

nication time $\mathcal{T}_{\text{comm}}(\mathbf{R}, ...)$, then a comparison between both terms can be used to ensure proper compute to overhead-ratio. For example, $\mathcal{T}_{\text{cpu}}(\mathbf{R}, ...) > 9 * \mathcal{T}_{\text{comm}}(\mathbf{R}, ...)$ states that the time spend in communication should not exceed 10% of the runtime of that region $(\mathcal{T}_{\text{cpu}} + \mathcal{T}_{\text{comm}})$. Again, moving from a generic model to a specific execution instance, the modeled components can be replaced with measurements of the specific components from that region.

Performance critical component misconceptions correspond to the developer relying on a partial model $\mathcal{T}'$ describing a subset of the full, but unknown, model $\mathcal{T}$. This model, while not 100% correct, sufficiently approximates the full model, if the error $\mathcal{E}_t = \mathcal{T} - \mathcal{T}'$ is small enough, i.e. $\mathcal{E}(\mathbf{R}, ...) \ll \mathcal{T}(\mathbf{R}, ...)$. For a specific execution the generic model can be substituted with the measurements.

The metric used so far, was the time spent in specific components of the code, i.e. compute and communication. While a plethora of possible metrics exists on current hardware platforms, such as hardware performance counters counting the number of floating-point operations, or memory accesses, their precise interpretation is often hardware-specific, compiler depended and requires considerable expertise. This does not imply, that these more detailed metrics should not be used, but we consider them too complex for this step towards active performance documentation. This is especially the case, as the runtime of specific components, if measurable, can function as a stand in for these more precise metrics. On today's HPC systems three principal components can be considered as measurable: The CPU with its compute units, the network components, and the I/O system. Time measurements of these three components aggregate to the total runtime of a specific application run, and therefore can be used to describe the full application behavior.

3.3 Active Documentation Example

Using these simplifications, it is possible to express the desired performance checks directly in the program. To demonstrate this, we use the pseudo-code of Listing 1 as a

```
1  for (time_step < end) {
2          #pragma apd balanced(t_cpu,0.1,NEXT_STATEMENT)
3          while(not_converged) {
4                  exchange_local_boundaries(...);
5                  compute_local_solution(..);
6                  communication_error(...);
7          }
8    #pragma apd balanced(t_cpu,0.1,NEXT_STATEMENT)
9    compute_global_contribution(...);
10   communicate_global_contribution(...);
11 }
```

Listing 2: Demonstrator Pseudocode with Work-balance APD

This pseudo-code is augmented with two APDs defining the expected work-balance. Computations are highlighted in green color, communication and synchronization in red color, and APD code is highlighted in blue. `NEXT_STATEMENT` specifies, that the APD operates only on the next statement, and sub-elements.

demonstrator. Listing 1 mimics the work-flow of typical fluid-dynamics applications, and depicts a simple boundary-region based parallelization of a solver with local computations (line #3-4), global convergence check (line #5) and global operations (line #7-8).

For this example, a lack of **load balancing** implies, that one of the computational entities must compute more than the others. This entity, either a thread or a process, will spend more time in the routines of line #4 and #7 of Listing 1. To state for this example, that the workload must be balanced, one could either specify that the loop body of the while-loop, that the whole while-loop or that the global computation must be balanced. The granularity of the scope chosen will effect the overhead. In this case, either option is viable, as the loop contains a call to a communication routine, which are typically more expensive than a local measurement and comparison. Therefore, the cost of tracking the runtime and exchanging it will be in the worst case on the same order of magnitude as the loop body, but will in most situations be masked by the communication and actual computation overhead. The same consideration applies to the second communication routine of line #8. Borrowing from the C-pragmas, the pseudo-code syntax **apd balanced(metric,deviation,region)**[5] describes that for the designated region, e.g. the next statement, a computation entity, i.e. a tread of process, may only deviate up to 10% from the slowest in terms of the given metric. Listing 2 offers an example for such ab active performance documentation using the CPU time metric t_{cpu}.

In the case of **over parallelization**, the computational aspects shrink, e.g. in the case of strong scaling due to constant domain partitioning with increasing number of processes. The ratio of work, i.e. the time spent using the CPU, shifts from the computation code, lines #5 and #9 in Listing 1, to the communication code in lines #4, #6 and #10. In general, as

[5]The pragma is used in lieu of an actual implementation using a domain specific language or other programming constructs native to the host language.

```
1  #pragma apd cold(t_comm,0.1,NEXT_STATEMENT)
2  for (time_step < end) {
3          #pragma apd balanced(t_cpu,0.1,NEXT_STATEMENT)
4          while(not_converged) {
5                  exchange_local_boundaries(...);
6                  #pragma apd hot(t_cpu,0.98,CURRENT_SCOPE)
7                  compute_local_solution(..);
8                  communication_error(...);
9          }
10   #pragma apd balanced(t_cpu,0.1,NEXT_STATEMENT)
11   compute_global_contribution(...);
12   communicate_global_contribution(...);
13 }
```

Listing 3: Demonstrator Pseudo-code with Work-balance APD

This pseudo-code is augmented with a hot- and cold-spot APD defining the expected ratio of compute to communication. Computations are highlighted in green color, communication and synchronization in red color, and APD code is highlighted in blue. `CURRENT_SCOPE` expands the APD to cover all elements of the current scope.

long as the computation dominates, this is considered acceptable to a certain degree, but at the latest when communication dominates, the CPU no longer contributes effectively to the computational solution. The precise communication to compute ratio is depended of the specific situation. A guard against such behavior is the measurement of time spent computing (t_{cpu}) and communicating (t_{comm}) and a comparison between both times. Without further evidence, it is for $t_{cpu} \gg t_{comm}$ safe to assume, that the compute to communication efficiency of the monitored code aspect is sound. Rephrased, the fraction CPU-time to the wall-time of the region must be much larger than 50%. This is more commonly known as a *hot-spot*; in this case it is a hot-spot of CPU usage.

Thus, by stating that for the given region a CPU-time hot-spot exists, a clear and measurable definition of its behavior is specified. As a side effect, a developer reading the APD in the source-code with APD will be able to understand the intended behavior. In a complementary fashion, the same behavior could be defined by a communication *cold-spot*, stating that communication should not exceed a specific fraction of work.

For example, using hot- and cold-spots in Listing 2, it is possible to specify good computational efficiency. Using the pseudo-code syntax **apd hot**(**metric**, **deviation**, **region**), a computation hotspot is defined with a 98% hotness, i.e. 98% of this regions runtime must be spent in computation. In absence of other contributors, this also implicitly defines a communication cold-spot of 2%. The APD in line #1 of Listing 3 states, that for the whole example the communication time should at maximum consume 10% of runtime. If the code is executed with twice the number of processes, the local domain will only contain half the number of elements to compute, cutting the runtime of the computation in half. Assuming the communication time remains constant, the remaining computa-

```
1  #pragma coverage(t_cpu,0.9,CURRENT_SCOPE)
2  main(...) {
3    startup(...)
4    #pragma apd cold(t_comm,0.1,NEXT_STATEMENT)
5    for (time_step < end) {
6      #pragma apd balanced(t_cpu,0.1,NEXT_STATEMENT)
7      while(not_converged) {
8        exchange_local_boundaries(...);
9        #pragma apd hot(t_cpu,0.98,CURRENT_SCOPE)
10       compute_local_solution(..);
11       communicate_error(...);
12     }
13     #pragma apd balanced(t_cpu,0.1,NEXT_STATEMENT)
14     compute_global_contribution(...);
15     communicate_global_contribution(...);
16     output_timestep(time_step,...)
17   }
18   shutdown(...)
19 }
```

Listing 4: Demonstrator Pseudo-code for APD guarding against PCCM

This pseudo-code is augmented with a single APD defining the global coverage of all APDs in the code. Computations are highlighted in green color, communication and synchronization in red color, and APD code is highlighted in blue.

tion time must be 18 times the communication time to pass the criterion. Double that number for each doubling of the number parallel processes. It is obvious, that eventually the communication time will outclass the runtime, and thus fail the comparison. Thus, by focusing on the simple concept of "hot-" and "cold-spots" in combination with metrics representing the critical components of HPC systems, i.e. networking, I/O, memory, or CPU performance, users can define active performance documentation that prevents issues, such as over-parallelization.

The pseudo-code of Listing 1 is too simple possible to demonstrate a guard against performance critical component misconceptions. We extend the pseudo-code (see Listing 4), with a startup-routine, an output-routine at the end of the time-step loop body, and a shutdown routine at the end. Here, the APD **apd coverage**(**metric**, **percentage**, **region**) describes the coverage of all other APD in the code of the corresponding region. If, as in this case, a coverage of 90% is specified, then this states that for the given metric 90% must be covered by other APD. For Listing 4, this means that 90% of all runtime must be spent in the hotspot (line #10). If, for example, the start-up routine were to become computational expensive and would consume 15% of t_{cpu}, then the coverage APD would fail and notify the user of one ore more undiscovered computational intensive regions.

```
1 // #pragma apd balanced(t_cpu,0.1,NEXT_STMT)
2 double local_start_time=get_wtime();
3 compute_global_contribution(...);
4 double delta_t=get_wtime()-local_start_time;
5 double global_max_time;
6 MPI_Allreduce(&delta_t,&max_t,1,MPI_DOUBLE,MPI_MAX,APD_COMM);
7 if (delta_t<(1-0.1)*max_t) perror("APD␣failed");
8 communicate_global_contribution(...);
```

Listing 5: APD to native code transforamtions example

This pseudo-code showcases the transformation of a work-balance APD to native code. Computations are highlighted in green color, communication and synchronization in red color, and APD code is highlighted in blue.

3.4 Implementation Aspects

So far, we used pseudo-code pragmas to specify and anchor an APD in the source code. Such a transformation can be implemented in a compiler, such as the LLVM compiler.

However, the concepts that the pragmas represent, can also manually be implemented in the source code, using the native programming language. For example, the APD for load-balancing requires for each process two measurements of the required metric, e.g. CPU-time, and a communication call to exchange the locally measured data. Listing 5 shows a possible implementation. In line #2 the walltime before the monitored regions is acquired. Line line #4 measures the walltime after the region and computes the time spent in the `compute_global_contribution` section of the code. Lines line #5-7 declare a variable to store the global maximum, which is then obtained via an `MPI-Allreduce` call. In this case, we use a unique communicator to isolate the communication calls from the APD system from the rest of the program to avoid communication problems. Line line #7 implements the check against the given criterion and prints an error message, if it fails.

4 Conclusion

Performance of software, especially parallel software, is challenging to obtain and difficult to maintain. *Performance Stewardship*, i.e. the methodical approach for maintaining performance, is becoming an important aspect of scientific software. *Active performance documentation* (APD) offers a shift from a proactive monitoring approach, where one actively looks for performance issues, to a reactive approach, where one only has to react to occurring issues. We propose the concept of augmenting the code with measurement facilities and automated analysis capability to automatically track all executions of the software. However, generic APD is complex and subject of research. But for reoccurring mistakes that can seriously hamper performance, simplifications can be applied that make APD viable. We demonstrate the use of such APD on a demonstrator pseudo-code for *load imbalances*, *over-parallelization* and *performance critical component misconceptions*.

Even though the concept of APD is subject of current ongoing research, we demonstrate that the concept can already be applied to codes, although not yet with automated support by compilers or tools.

In conclusion, it is critical, according to the popular wisdom "knowing of the existence of a problem is the first step in solving it", to detect performance issues in every execution of a code to mitigate problems as soon as possible. APDs offers exactly this knowledge, if properly implemented, and provides the necessary support for *Performance Stewardship*.

Comprehensive Grid Resolution Study of WALE Model for Large Eddy Simulation of Turbulent Pipe Flow

Daiki Iwasa*, Yusuke Nabae**, Koji Fukagata***

*Keio University, **Keio University, ***Keio University

ABSTRACT

In recent years, reduction of CO2 emission has become an urgent issue in order to mitigate the global warming. It is said that three quarters of CO2 emission out of transport is from the road sector. The Cross-ministerial Strategic Innovation Promotion Program (SIP) in Japan aims at improving the thermal efficiency of IC engines up to 50 percent, where an IC engine simulator, named HINOCA, is being developed so as to enable prediction and improvement of IC engines. This simulator consists of different physical models of IC engines, such as turbulent flow, ignition, and combustion. As for the turbulence simulation, the wall-adapting local eddy-viscosity (WALE) model is adopted for the subgrid-scale model in large-eddy simulation (LES). However, for HINOCA to complete a simulation within a realistic computational time, it is inevitable to choose the grid spacings much coarser than that is well accepted. Therefore, we need to assess the accuracy of WALE model in the case where the computational grid is very coarse. In the present study, we perform a comprehensive grid resolution study of the WALE model in a turbulent pipe flow. The LES is performed under the constant flow rate at the bulk Reynolds number of 5300. The computational grid is uniform in the streamwise (longitudinal) and spanwise (azimuthal) directions while non-uniform in the wall-normal (radial) direction. A top-hat filter is used for the spatial filter. The results show that the turbulent statistics such as the mean velocity profiles and the second order moments significantly depend on the spanwise grid resolution, while less sensitive to the streamwise grid resolution. The coarsest streamwise and spanwise grid resolutions producing reasonable statistics are found to be about 56 and 18 wall units, which is in accordance with conventional LES studies. The sensitivity to the wall-normal grid spacing is found to be much less than what is usually believed. Surprisingly, the statistics are reasonably well reproduced using only 6 computational points in the radial direction if only the first computational point is located within 5 wall units from the wall.

A Variational Multiscale Method for Dynamic Viscoelasticity and Quasi--static Elasto--plasticity Using Linear Tetrahedral Elements

nabil abboud*, guglielmo scovazzi**, oriol colomes***

*duke university, **duke university, ***duke university

ABSTRACT

We propose an extension of the dynamic variational multiscale stabilization (D--VMS) to nearly/fully incompressible viscoelastic materials using quadrilateral/tetrahedral finite elements. We test the approach on two different viscous constitutive laws, namely, models based on Prony series and models based on the multiplicative decomposition of the deformation gradient. In addition, we propose a new variational multiscale approach for quasi--static elasto--plasticity. The main features of this method are the definition of an effective shear modulus as well as the use of fine--scale pressure. Our method is based on a mixed formulation, in which the momentum equation is complemented by a pressure equation in rate form for viscoelasticity and static form for elasto--plasticity. The unknowns are approximated with piecewise linear, continuous finite element functions. For viscoelasticity, in order to prevent spurious oscillations, the pressure equation is augmented with a stabilization operator specifically designed for viscoelastic problems, in that it depends on the viscoelastic dissipation.

Modeling of Light Aircraft Landing Gears: Convenient Damping Settings According to Runway Type

nadia arif*, frédéric lebon**, Hélène ELIAS-BIREMBAUX***, iulian rosu****

*Aix-Marseille Univ., CNRS, Centrale Marseille, LMA, Marseille, France, **Aix-Marseille Univ., CNRS, Centrale Marseille, LMA, Marseille, France, ***Aix-Marseille Univ., CNRS, Centrale Marseille, LMA, Marseille, France, ****Aix-Marseille Univ., CNRS, Centrale Marseille, LMA, Marseille, France

ABSTRACT

Light aircrafts are designed to be used in both developed and undeveloped areas of a country. Hard landing conditions such as shocks and rebounds may occur on irregular terrains. The main role of the landing gear is to dissipate the energy of the landing impact. Although, a part of shock energies is absorbed by under-inflated tires. The aim of this work is to study light aircraft landing gears, and suggest convenient damping settings according to runway type. The study is carried out through three steps. Firstly, Bush tire are modeled with finite elements taking into account tire geometry and materials specifications. The tire-runway contact is modeled using hard contact and friction coefficients are determined experimentally. Secondly, three different landing gear systems are modeled: a classical spring steel landing gear, a landing gear with bungee cords and a recent landing gear equipped with a real damper. Traditionally, landing gear numerical simulations have been carried out with Multi-body Dynamics (MBD) software. In this study, finite elements are used combined with connectors, mass concentrations, springs/dampers and rigid elements. Thus, stress, deformation and energy within landing gears components are obtained, taking into account the nonlinearities of the system. Finally, aircraft dynamic rolling simulations are conducted. The systems' transient dynamic responses on rolling over obstacles are evaluated, as well as efforts and rebound amplitudes submitted to the aircraft body. An efficiency comparative study between the landing gears is conducted. On the other hand, the damper's stiffness and damping laws are investigated. The influence of these parameters on the landing gear dynamic performance in different rolling conditions is highlighted. Thus, aircraft rolling simulations on different types of runways (by introducing variable friction coefficients and runway shapes) are conducted. These simulations allow settings' adjustment based on the landing gear dissipation efficiency for each case.

ABSTRACT

Introduction: Cardiovascular disease (CVD) is the most common cause of death worldwide, and its prevalence is increasing [1]. Research indicates that the onset of CVD can be slowed down or even prevented when detected in an early stage. An early indicator for CVD is increased stiffness of the large elastic arteries such as the aorta and the common carotid artery (CCA). Therefore, arterial stiffness detection is being developed as screening method through various methodologies such as carotid-femoral pulse wave velocity (PWV) detection using tonometry and distensibility coefficient (DC) detection using ultrasound (US), amongst other methods [2]. Using US, DC is often estimated by imaging a 2D, longitudinal cross-section of the CCA. The position of the upper and lower CCA wall is measured during diastole and systole. Assuming radial distension of the CCA, with the CCA maintaining its circular cross-section throughout the heart-cycle, the relative change in arterial cross-sectional area for a given pressure change can be readily estimated, or an indicator for arterial stiffness: the DC [3]. Since the stiffness of the CCA is much higher than the stiffness of the bulk surrounding tissue, a steady circular cross-section throughout the heart-cycle can be assumed. However, the influence of nearby structures with different stiffness than the CCA cannot be ignored. In this study, the influence of a realistic measurement situation on a US DC measurement is evaluated. Methods: A 2D static finite element model (FEM) of the CCA and its surrounding anatomy is constructed, based on 3 cross-sections of the left and right CCA of 10 healthy volunteers, resulting in 60 data-points with significantly different anatomical features. DC as estimated with US, is then compared with the “ground-truth” DC as based on the true area change. Hereby, the influence of nearby structures with different stiffness than the CCA is included, as well as the pressure of the US probe. Results and conclusion: Stiffness is overestimated using US in the majority of the cases as compared to the “ground-truth” stiffness. However, the detected difference is smaller than 5% which is not relevant for medical applications [4]. Therefore, we conclude that our results do not show contraindications for the use of US for DC detection. [1] World health organisation n.d. http://www.who.int/en/. [2] Laurent S et al. Indentation Response of Freestanding Two-dimensional Materials with an Adhesive Boundary Condition

guoxin cao*

*Tongji University

ABSTRACT

The mechanical behavior of freestanding (FS) two-dimensional (2D) materials is commonly investigated through indentation tests performed via atomic force microscopy (AFM), where a 2D-material is placed on a substrate with a cylindrical hole and indentation is performed over the FS region of the 2D-material over the hole. Here, we perform theoretical and finite element analyses to show that the conventional assumption of a clamped boundary condition in existing models of such tests is inappropriate and should be replaced with an adhesive boundary condition in which the 2D-material can be partially detached from the substrate. A new analytical model which accounts for the adhesive boundary condition is then developed and shown capable of describing the indentation response of FS 2D-materials.

New Rortex Based Omega Method

Sita charkrit*, Chaoqun Liu**, XIangrui Dong***, Yisheng Gao****

*University of Texas at Arlington, **University of Texas at Arlington, ***University of Texas at Arlington, ****University of Texas at Arlington

ABSTRACT

In this paper, a new vortex identification method named Rortex-Omega method is introduced base on the Rortex, which is a mathematical definition proposed by our group. The basic idea of this new Omega is the normalization of Rortex. The new Omega is defined as a ratio of the rotation square over the sum of rotation square and anti-symmetric shear square. Compared with other vortex identification methods, this method has several advantages: it can capture both strong and weak vortex structures in turbulence and transition flow to be a case independent and a normalized method; It can be further used in studying the turbulence vortex structures, turbulence modeling and correlation analysis as a physical quantity just like pressure, density, etc.

Staggered Multi-material ALE Code for Large-deformation Problems with Changing-topology Interfaces

junxia cheng*, Heng Yong**, Shuanghu Wang***, Liang Pan****

*Institute of Applied Physics and Computational Mathematics, **Institute of Applied Physics and Computational Mathematics, ***Institute of Applied Physics and Computational Mathematics, ****Institute of Applied Physics and Computational Mathematics

ABSTRACT

The Arbitrary Lagrangian-Eulerian(ALE) Formulation has been the research hotspot since the work of Hirt etc., which emerged to alleviate the drawbacks of traditional Eulerian and Lagrangian formulations. The algorithm described by Hirt etc. couldn't rezone across material interfaces, which was called simple ALE (SALE). A powerful extension to SALE is to incorporate VOF(volume of fluid) or MOF(moment of fluid) capability into the mixed cells containing multiple materials, which was called multi-material ALE(MMALE)[1]. Staggered Lagrangian schemes have been extensively used in the simulations of elastic-plastic multi-material problems since the numerical simulation emerged, but Lagrangian schemes couldn't tackle the problems of changing-topology interfaces. So, Multi-material ALE method, which is effective to the large-deformation problems with changing-topology interfaces, has been the trend of computational mechanics in recent years. Aiming to meet the need of numerical simulations of mutli-material large-deformation problems, we develop the staggered multiple-material ALE code. We use MOF interface reconstruction method [3], the equivalent strain closure model for mixed cells (containing multiple materials) and conservative flux-based multi-material remapping method [2] to develop the staggered multi-material ALE code. Numerical results of shock tube, Rayleigh Taylor incompressible instability problem and interaction problem of a shock wave with Helium bubble, prove that our multi-material ALE code is valid in the multi-material large-deformation problems with changing-topology interfaces. Our MMALE code will be a useful tool in the large-deformation numerical simulation field. The Multi-material ALE scheme can treat the multi-material problems with the views of Lagrangian, Eulerian or ALE flexibly, so it is booming all over the world in recent years, but there are still some difficulties in the development of MMALE, especially the closure model is a challenge for the materials with absolutely different properties. In the future, we will study the closure models to extend the applications of MMALE. Key words: large-deformation problems, multi-material ALE, MOF reconstruction method

Computational Methods for Fracture in Fluid-Saturated Porous Media

Rene de Borst*

*University of Sheffield, Department of Civil and Structural Engineering

ABSTRACT

Since the pioneering work of Terzaghi and Biot, the flow of fluids in deforming porous media has been given considerable attention. Nevertheless, flow in fractured or fracturing porous media has received less attention, although the physics of the flow within such discontinuities can be very different from that of the interstitial fluid in the surrounding deforming bulk, and in spite of its technological and societal importance as in energy and environmental issues. Herein we develop a general model for flow in progressively fracturing porous media. Since the cross-sectional dimension of the fracture is small compared to its length, the flow in the crack can be averaged over the width. A two-scale model results, including momentum and mass couplings between the subgrid scale and the macroscopic scale. Numerically, the two-scale model imposes some requirements on the interpolation of the displacement and pressure fields. Moreover, it will be shown that the interpolation of the pressure across the crack has implications for the physics that can be accommodated [1]. Discretisation methods are needed to model a crack, which is essentially an internal free boundary. Interface elements are an option, but have restrictions in terms of flexibility. Exploiting the partition-of-unity property allows the crack path to be decoupled from the underlying discretisation. Another possibility is isogeometric analysis. We develop an isogeometric formulation for porous media, including stationary and propagating cracks, such that it is possible to have fluid transport in the cracks. Within this framework crack initiation and propagation can be modelled in two ways: either via lowering the order of the interpolation [2], or by using isogeometric interface elements [3]. Modelling and Numerical Analysis of Sloshing in LNG Containment Tanks

Rien de Böck*, Arris Tijsseling**, Barry Koren***

*Eindhoven University of Technology, **Eindhoven University of Technology, ***Eindhoven University of Technology

ABSTRACT

Assessment of the impact loads of sloshing liquefied natural gas (LNG) on containment tanks of seagoing LNG carriers is a major structural design challenge. Especially breaking LNG waves can cause severe damage. A lot of research into this is currently being done, using (scaled) experiments and numerical studies. Due to the many physical parameters involved: liquid compressibility, gas compressibility, the ratio of the densities of the phases, phase transition and more, it is impossible to scale the entire process in a unified way. To study these parameters separately we perform numerical modelling and analysis of multiphase compressible fluid-flow problems. To start with, a five-equation two-fluid flow model [1] is discretized in space with an innovative higher-order accurate finite-volume method. The higher-order model is obtained through spatial reconstruction with a limiter function, for which latter some novel formulations are presented. We study the one-dimensional case of a liquid column impacting a gas pocket entrapped at a solid wall. This is known as the generalized Bagnold model [2]. It mimics the impact of a breaking wave in an LNG containment system, where the gas pocket is entrapped below the wave crest and the tank wall. Furthermore, the impact of a shock wave on a gas bubble immersed in air is simulated, in two dimensions, and compared to experimental results from [3]. Two cases are considered, one where the bubble gas is heavier (R22), and one where it is lighter (Helium) than the ambient air. The bubble deforms and surface instabilities form and develop. The computational results obtained have a good resemblance to the references. The correct wave speeds are computed and the surface instabilities are qualitatively similar. References 1. A.K. A Geometric Nonlinear iFEM Approach Using Solid Elements

Cornelis de Mooij*, Marcias Martinez**, Rinze Benedictus***

*Delft University of Technology, **Clarkson University, ***Delft University of Technology

ABSTRACT

A Geometric Nonlinear iFEM Approach Using Solid Elements Cornelis de Mooij1, Marcias Martinez2,1 and Rinze Benedictus1 1 Delft University of Technology 2 Clarkson University Abstract. Structural Health Monitoring (SHM) is a growing field of research, as it has the potential to simultaneously improve the reliability of structures and reduce their maintenance cost. SHM requires accurate stress and strain information, preferably for the entire structure. Unfortunately, it is often infeasible to instrument every part of the structure, making it necessary to estimate the stress and strain fields based on data from a limited number of sensors. One promising technique for making this estimate is the Inverse Finite Element Method (iFEM), which can be applied to any combination geometry and loading conditions. It can also process several different types of sensor data. For this study, an iFEM algorithm was developed that uses solid elements and is capable of geometrically nonlinear analyses. These capabilities are both novel and necessary for aircraft wings and wind turbine blades. These structures often have thick regions and experience large deflections and rotations. Solid elements are more appropriate for modelling thick regions than shell elements, which are used in most of the iFEM literature. Geometric nonlinearity is necessary to accurately model large deflections and rotations. As a proof-of-concept, the strain and displacement distributions were determined numerically for several geometrically nonlinear benchmark tests from the literature, using a FEM code that was developed in-house and verified using Abaqus CAE. A varying number of virtual sensors were simulated based on the finite element results, in lieu of experimental data. The data from these sensors were used as input for the iFEM algorithm, which was also developed in-house. It was shown that the iFEM results match the literature values for geometric nonlinear conditions, even when only a limited number of virtual sensors were used.

Numerical Analysis of Residual Stresses of SS304L on Selective Laser Melting

Diego de Moraes*, Madhukar Somireddy**, Aleksander Czekanski***

*York University, **York University, ***York University

ABSTRACT

Residual stress is one of the most noticeable issues found in Additive Manufacturing components, especially when working with metal powder alloys, which will need high temperature in order to build the part. For this reason, several testing procedures are necessary to be implemented in order to validate a new alloy use in Metal Powder Bed Processes. The usual tests are minimum wall thickness assessment, cracking and warping analysis, process parameter optimization and melt pool analysis. The testing procedures usually demands long-term development and planning, for this reason Numerical Models are being implemented in numerous scales nowadays, from Discrete Element Modeling of powder to Thermal and Mechanical modeling, to minimize the range of parameters used in testing and optimize the process. These simulations are important either for the pre-analysis and for evaluation of parameter selection utilizing the selected new alloy, thus the objective of this study is to evaluate the effectiveness of this approach. The model proposed is a thermomechanical simulation of Selective Laser Melting process (SLM) to obtain the residual stresses when scanning a single track through the powder bed. The material selected is the Stainless Steel 304L, which is not commercially available on SLM manufacturers yet and it is a promising alloy to be largely used for Additive Manufacturing technology due its low cost along with the SS316L. The laser is modeled using the heat flux formulation based in a Gaussian profile described by Goldak et al, utilizing a double ellipsoid shape to effectively match the shape of the moving heat source present in SLM process. Close attention is required when inputting the powder properties, especially emissivity and thermal conductivity which has to be conditioned given parameters like chamber pressure, thermal gas conductivity, powder diameter, porosity and initial temperature. A Fortran subroutine is implemented and linked to the FEM solver to account for all the X-Y orientations as well the heat source input parameters. The validation is performed by literature, especially with the study of Simsom et al and Yakout et al, who performed experimental measurements of the residual stresses through XRD. The results are presented for 3 power different power inputs (100W, 200W and 400W), in order to analyse the impact on the final residual stresses on commercially available equipment.

Numerical and Experimental Aspects of Modeling and Fabricating Soft Robots

Kristin de Payrebrune*

*TU Kaiserslautern

ABSTRACT

The recent interest in soft robots arises from their adaptability, versatility and flexibility, which is very beneficial for new applications of human-robot interaction, healthcare or field exploration. Many prototypes have already proven the feasibility of soft robots to grasp indistinct objects, to walk on uneven surfaces, or to interact with humans. Additional research on mathematical models of these continuous deformable robots are in progress to predict their performance in real live and operating situations. At the Institute of Applied Structural Mechanics, pneumatic actuated and tendon driven soft robots have been fabricated and analyzed, and a rod model has been developed to describe the robot under loading and walking conditions. For a quadruped soft robot, we will present design aspects to optimize the performance of the soft robot and results of the experimental analyses. Furthermore, a simple rod model will be presented with which the deformation of the soft material structures can be described under pressurization. To parameterize the rod model, special experiments are conducted and will be discussed. Beside the research on soft robots, a tendon driven robot has been developed that moves autonomously on a horizontal or inclined surface. Via servomotors, the three segments of the robot can be controlled such that the robot is able to walk straight forward or on a circular path. The capability to walk on an inclined surface was tested on several surface materials and the results will be presented and related to the friction coefficient between surface and contacting limb.

Preconditioned Iterative Solvers for Immersed Finite Element Methods with Application to Flow Problems

Frits de Prenter*, Clemens Verhoosel**, Joseph Benzaken***, John Evans****, Harald van Brummelen*****

*Eindhoven University of Technology - University of Colorado Boulder, **Eindhoven University of Technology, ***University of Colorado Boulder, ****University of Colorado Boulder, *****Eindhoven university of Technology

ABSTRACT

Immersed methods are useful tools to preclude expensive (re-)meshing operations for flow problems around complex objects, flow problems on scanned domains, and fluid-structure interaction problems with large deformations. A common pitfall of immersed techniques is, however, ill-conditioning of the linear system [1]. This impedes the convergence of iterative solvers, and often compels researchers to resort to direct solvers. This hinders the efficient and inexpensive computation of solutions of large sparse systems, as the computational cost of direct solvers does not scale well with the size of the linear system, making them unsuitable for the increasingly large problems being solved by immersed methods, e.g. [2]. In [1] we have analyzed the fundamental cause of ill-conditioning of immersed finite element methods and, based on this analysis, in [3] we have developed a preconditioner that is tailored to immersed flow problems. We demonstrate that this preconditioner brings the condition number down to that of standard, mesh-fitting, finite elements, such that the linear system can be solved iteratively. Like standard finite elements, the conditioning of this preconditioned system still depends on the grid size however. In this contribution we shortly describe the cause of the conditioning problems and the developed preconditioner, and extend this approach to investigate possibilities to apply the preconditioner as a smoother in a multigrid cycle to develop a scalable solver that is robust to both the grid size and how elements are cut. A Physical Multifield Model Predicts the Development of Volume and Structure in the Human Brain

Rijk de Rooij*, Ellen Kuhl**

*Stanford University, **Stanford University

ABSTRACT

The human brain, amongst that of most other mamallian brains, assumes a highly folded structure through- out its development after being initially smooth. This folded structure offers the great benefit of allowing more surface area for a given brain volume. Indeed, the cortical layer at the brain surface accommodates the cell bodies of the nerve cells that provide the brain with its processing capabilities. Several pathologies in neurodevelopment have been associated with abnormalities in cortical folding and behavioral disorders. A thorough understanding of neurodevelopment is therefore critical towards understanding and, potentially, treating such disorders. The prenatal development of the human brain is characterized by a rapid increase in brain volume and a development of a highly folded cortex. At the cellular level, these events are enabled by symmetric and asymmetric cell division in the ventricular regions of the brain followed by an outwards cell migration towards the peripheral regions [1]. The role of mechanics during brain development has been suggested and acknowledged in past decades, but remains insufficiently understood. Here we propose a mechanistic model that couples cell division, cell migration, and brain volume growth to accurately model the developing brain between weeks 10 and 29 of gestation [2]. Our model accurately predicts a 160-fold volume increase from 1.5cm3 at week 10 to 235cm3 at week 29 of gestation. In agreement with human brain development, the cortex begins to form around week 22 and accounts for about 30% of the total brain volume at week 29. Our results show that cell division and coupling between cell density and volume growth are essential to accurately model brain volume development, whereas cell migration and diffusion contribute mainly to the development of the cortex. We demonstrate that complex folding patterns, includ- ing sinusoidal folds and creases, emerge naturally as the cortex develops, even for low stiffness contrasts between the cortex and subcortex. RF Signal Compression Using Multiresolution Wavelet Decomposition for Efficient Piecewise Pulse Wave Imaging

Ketson dos Santos*, Iason Apostolakis**, Elisa Konofagou***, Ioannis Kougioumtzoglou****

*Columbia University, **Columbia University, ***Columbia University, ****Columbia University

ABSTRACT

During the contraction-relaxation cycle the heart produces pressure pulses, also known as pulse waves, which travel through the vessel wall with a certain velocity. This Pulse Wave Velocity (PWV) can be estimated by the piecewise Pulse Wave Imaging (pPWI) technique based on a high frame-per-second (FPS) (e.g., 8000 fps) ultrasound imaging [1]. In this regard, one can map the localized arterial wall stiffness in vivo aiming at the detection and monitoring of localized vascular diseases. Nevertheless, certain limitations exist related to data transfer and storage capacity due to the high FPS adopted in the data acquisition step. Therefore, large time-varying RF-frames in the order of gigabytes and containing only a dozen milliseconds of data are inevitably produced in one single clinical evaluation. To circumvent such big data limitations a data compression technique based on a multiresolution 1-D wavelet analysis [2] is proposed considering the strong correlation of the RF-frames in the time domain. A numerical example involving real data is considered, while the signal-to-noise ratio (SNR) and the achieved compression ratio are adopted as performance measures. [1] I. Z. Apostolakis, S. D. Accuracy Verification of Sensitivity Analysis for Topology Optimization Problems Considering Dynamic Structural Behavior

takuma endo*, junji kato**, takashi kyoya***

*Tohoku University, **Tohoku University, ***Tohoku University

ABSTRACT

For topology optimization problems considering dynamic structural behavior, the accuracy of sensitivity is very important. It is suggested that there is a possibility that an error may occur in the design sensitivity in the dynamic problem. However, details such as specific parameters that can cause errors are still not clear. The purpose of this study is to investigate errors in the sensitivity of the objective function to design variables. Here, we verify the accuracy of the design sensitivity from the two viewpoints, the time discretization method and the dynamic governing equation terms. Regarding the time discretization method: central difference method (explicit method) and the Newmark ? method (implicit method) are used for numerical analysis. We examine how influence the choice of explicit method and implicit method has on design sensitivity. Regarding the governing equation: inertia term and viscosity term can be considered a cause of errors. We show concrete numerical calculation example and confirm the influence on the design sensitivity when considering these terms.

Data-Driven Macro-Micro Modeling of Process-Structure Linkages in Directed Energy Deposition of Ni-based Supperalloy

zhengtao gan*, yanping lian**, wing kam liu***

*Northwestern University, **Northwestern University, ***Northwestern University

ABSTRACT

Additive manufacturing (AM) is of tremendous interest in engineered structural materials. However, multi-scale complicated physical phenomena simultaneously occur during the process and result in complex microstructure forming spatially and an-isotropic mechanical properties within the build. The relationships between multi-physics processes, solidified microstructure and mechanical properties in AM have not been thoroughly understood. For addressing this need, a multi-scale modeling framework for process-structure relationships is proposed. (1) A part-scale thermal-CFD module considering heat transfer, fluid flow (Marangoni effect) and mass addition is proposed. (2) A Meso/Micro-scale grain/dendrite structure evolution module is proposed to simulation grain nucleation, epitaxial growth, and columnar to equiaxed transformation (CET). The temperature history, liquid metal velocity in the melt pool, columnar to equiaxed transformation, and size/morphology of dendrite during AM of Ni-based supperalloy can be predicted and validated by experimental results.

Dynamic Analysis of Stewart Stabilized Platform by Newton Euler Method

xiaoxu guo*, yue fa zhou**

*College of Aerospace Engineering and Civil Engineering, Harbin Engineering University, China, **College of Aerospace Engineering and Civil Engineering, Harbin Engineering University, China

ABSTRACT

Stewart parallel mechanism is characterized by its important research and application value. In the decades after being presented, many scholars have done a great deal of work1-3. In this thesis, we mainly study the dynamics parts in the application of stabilized platform, deriving a dynamic equation based on Newton Euler method with the pods' qualities and inertia tensors are taken into account in the formulation. For verifying the theoretical results, formulation has been implemented in a program written in MATLAB compared to the ADAMS simulation results, then plotting the driving force diagrams under the several different motion forms. From the final results, it can conclude that the simulation results coincide with the actual driving force of the stabilized platform, and we also analyse the reason of driving force when it's easy to go wrong, which provides a theoretical basis for the dynamic control of the stabilized platform. The disturbance motion state of the lower platform for which is provided by the motion simulator fixed with it. Keywords: Stewart stabilized platform, Newton-Euler method, Dynamics, Matlab, Adams

ABSTRACT

The numerical simulation of thermo-mechanical processes is based on the modeling of the couplings between several physical phenomena such as heat transfer, metallurgy and mechanics. The classical time-stepping methods enable accurate predictions of the physical variables but are generally time consuming because these processes often involve moving loadings leading to fast evolutions and high gradients of the physical variables, and consequently to the choice of very small time steps. For simulations of thermomechanical forming processes like welding, the thermal, mechanical and metallurgical fields associated with moving loadings can reach steady states. Several authors have therefore proposed eulerian or mixed lagrangian-eulerian computation methods to determine directly or incrementally the steady states ([1][2][3]). In this paper, an eulerian approach with nodal integration is presented. Using nodal integration, the transfers are still necessary but may be performed in a more rigorous way, and this method permits to use standard linear tetrahedral elements in plasticity. In order to demonstrate the performance of eulerian approach with nodal integration, we propose first to compare this method with an incremental approach of calculation of the steady states associated to the welding process. Then, a simulation of the steady state with an application to rolling is presented and discussed in relation to existing arbitrary lagrangian-eulerian approaches ([4] [5]). REFERENCES [1] J. Huetink, P.T. Vreede, J. Van der Lugt, Progress in mixed eulerian-lagrangian finite element simulation of forming processes, Int. J. for Numer. Meth . Engng 1990, Vol. 30, 1441-1457. [2] J.-M. The Cosserat Point Element (CPE) for Modeling Static and Dynamic Response of Structures at Finite Deformations

Mahmood Jabareen*

*Technion - Israel Institute of Technology

ABSTRACT

The theory of a Cosserat point has been used to develop a 3D brick Cosserat point element (CPE) for the static and dynamic numerical solutions of elastic structures that undergo finite deformations. The Cosserat approach postulates an average form of the deformation measure and connects the kinetic quantities to derivatives of a strain energy function. Once this strain energy has been specified, the procedure for obtaining the kinetic quantities needs no integration over the element region and it ensures that the response of the CPE is hyperelastic. Also, the constitutive equations of the CPE were designed to analytically satisfy a nonlinear form of the patch test. Specifically, the strain energy function is additively decomposed into two parts: one controlling the homogeneous deformations and the other controlling the inhomogeneous deformations. Developing a functional form for the strain energy of the inhomogeneous deformations has proven to be challenging. Recently, a functional form of the inhomogeneous strain energy function was developed, which causes the CPE to be a truly user friendly element that can be used with confidence for problems with finite deformation. It was observed that the three-dimensional brick CPE is a robust, an accurate element that can be used to accurately predict the response of thin plates and shells with only one element through the thickness. Also, the CPE does not exhibit unphysical locking or hourglassing for thin structures or nearly incompressible material response.

Urban Flow Simulations Using LES Lattice Boltzmann Method

Jerome Jacob*, Pierre Sagaut**

*Aix Marseille Univ, CNRS, Centrale Marseille, M2P2, Marseille, France, **Aix Marseille Univ, CNRS, Centrale Marseille, M2P2, Marseille, France

ABSTRACT

Urban flow simulation on full scale configurations are widely used in the literature to assess pedestrian wind comfort, pollutant dispersion and thermal comfort inside cities. Urban flows are very complex three dimensional turbulent flows with several physical processes such as building wake interaction or channeling mechanisms. Most of these simulations have been performed using Reynolds Average Navier-Stokes (RANS) approach due to reasonable computational cost whereas Large Eddy Simulation (LES) are mainly used for simplified areas such as isolated buildings or street canyon. In this work we propose the use of lattice Boltzmann method[1] (LBM) based on the resolution of Boltzmann equation which describes the evolution of particle distribution function instead of Navier Stokes equations. This method is a very efficient method for massively parallel simulation due to local and linear algorithm. Furthermore the use of immersed boundary conditions and embedded uniform meshes with a ratio of 2 for the grid step between two successive refinement levels permit to mesh complex areas such as city more easily that make LBM a very interesting method for urban flow simulation. In this work the Boltzmann equation is discretized on a D3Q19 lattice and a single relaxation time regularized collision operator[2] is used to ensure the stability of the model. Some properties of this regularized collision operator have been used to perform implicit and explicit wall modeled LES simulations inside the Shinjuku area, a 1 km² part of Tokyo city center. These simulations are compared with several RANS simulation available in the literature and validated by comparisons with wind tunnel and in-situ measurements provided by the Architectural Institute of Japan. Modeling the Biomechanics of a Four Chamber Cardiac Model with Myocardial Infarction

Arian Jafari*, Edward Pszczolkowski**, Adarsh Krishnamurthy***

*Iowa State University, **Iowa State University, ***Iowa State University

ABSTRACT

Abstract: Cubic-Hermite finite element meshes are widely used for simulating cardiac biomechanics due to their superior convergence characteristics and their ability to capture smooth geometries compactly compared to linear tetrahedral meshes. However, such meshes have previously been used only with simple ventricular geometries with non-physiological boundary conditions due to challenges associated with creating cubic-Hermite meshes of the complex heart geometry. The complex geometry of the heart, especially near atrial regions and valves necessitates the appearance of extraordinary nodes (nodes with 3 or >= 5 adjacent elements in 2D) in the mesh. Extraordinary nodes allow the mesh to capture the geometric characteristics of the heart accurately and apply physiologically accurate boundary conditions. However, consistently interpolating the finite element fields in the presence of extraordinary nodes requires additional mathematical formulation. In this work, we created a four-chamber cardiac model utilizing cubic-Hermite elements and simulated a full cardiac cycle by coupling the 3D finite element model with a lumped circulation model. The G1 continuity of the finite-element fields in the neighborhood of extraordinary nodes were maintained using an ensemble coordinate system with a linear global-to-local transformation. The myocardial fiber orientations were interpolated within the mesh using the Log-Euclidean method to overcome the singularity associated with interpolation of orthogonal matrices. Physiologically accurate boundary conditions were applied to the nodes along the valve plane. We then simulated a complete cardiac cycle of a healthy heart and of a heart with myocardial infarction. We compared the pumping function of the heart for both cases by calculating the work done by the ventricle (area enclosed inside the left ventricular Pressure-Volume (P-V) loop) and the base-apex shortening. We observed a 12% reduction in work done by the heart after myocardial infarction and a corresponding reduction in the base-apex shortening. The displacement of the infarcted region and the corresponding region in a healthy heart was also compared to understand the influence of myocardial infarction on the local displacements of the myocardium. The myocardial wall displacements obtained from the four-chamber cardiac model are comparable to actual patient data without requiring complicated non-physiological boundary conditions usually required in truncated ventricular heart models.

An Isogeometric Collocation Method for Karhunen-Loeve Discretization of Random Fields

Ramin Jahanbin*, Sharif Rahman**

*The University of Iowa, **The University of Iowa

ABSTRACT

Many uncertainty quantification problems in engineering and applied sciences require modeling spatial variability of random input parameters. For instance, the tensile and fracture toughness properties of engineering materials, the size and shape characteristics of mechanical components, and the wind and snow loads in structural systems all exhibit randomness that varies not only from sample to sample, but also from point to point in their respective domains. Therefore, random field treatment of spatial varying randomness is a vital ingredient in computational analysis. Loosely speaking, a random field represents a random quantity at each point of the domain and, therefore, engenders an infinite number of random variables. In practice, though, the number of random variables must be finite and manageable but also large enough to ensure an optimal or accurate approximation of the original random field. This process is often referred to as random field discretization. This paper presents an isogeometric collocation method for solving a Fredholm integral eigenvalue problem, leading to random field discretization by the Karhunen-Loeve expansion. The method involves a projection onto finite-dimensional a subspace of a Hilbert space, basis splines (B-splines) and non-uniform rational B-splines (NURBS) spanning the subspace, and standard methods of eigensolutions. Like the existing isogeometric Galerkin method [1], the NURBS-based collocation method also preserves exact geometrical representation of the physical or computational domain and exploits regularity of basis functions delivering globally smooth eigensolutions. However, in the collocation method, the construction of the system matrices for a d-dimensional eigenvalue problem requires at most d-dimensional domain integrations, as compared with 2d-dimensional integrations in the Galerkin method. Therefore, the introduction of the isogeometric collocation method for random field discretization offers a huge computational advantage over the existing Galerkin methods. Numerical examples illustrate the accuracy, efficiency, and convergence properties of the proposed isogeometric method for obtaining eigensolutions. Using Deep Neural Networks for Data-Driven Inverse Modeling of Turbulent Wake Dynamics

Rajeev Jaiman*, Tharindu Miyanawala**

*National University of Singapore, **National University of Singapore

ABSTRACT

An efficient deep learning technique for the model reduction of the Navier-Stokes equations for unsteady flow problems is proposed. The proposed technique relies on the Convolutional Neural Network (CNN) and the stochastic gradient decent method. Of particular interest is to predict the unsteady fluid forces for different bluff body shapes for 3D high-Reynolds number flows. The discrete convolution process with a non-linear rectification is employed to approximate the mapping between the bluff-body shape and the fluid forces. The deep neural network is fed by the Euclidean distance function as the input and the target data generated by the full-order Navier-Stokes computations for primitive bluff body shapes. The convolutional networks are iteratively trained using the stochastic gradient descent method with the momentum term [1] to predict the fluid force coefficients of different geometries and the results are compared with the full-order computations. We attempt to provide a physical analogy of the stochastic gradient method with the momentum term with the simplified form of the incompressible Navier-Stokes momentum equation. We also construct a direct relationship between the CNN-based deep learning and the Mori-Zwanzig formalism [2] for the model reduction of dynamical system. A systematic convergence and sensitivity study is performed to identify the effective dimensions of the deep-learned CNN process such as the convolution kernel size, the number of kernels and the convolution layers. We perform the CNN predictions initially for low Re (laminar wake) and then for high Re (turbulent wake) flows. Within the error threshold, the prediction based on our deep convolutional network has a speed-up nearly four-orders of magnitude for the low Re and five-orders of magnitude for the high Re compared to the full-order results. The CNN only consumes a very small fraction of computational resources as well. The proposed CNN-based approximation procedure enables to perform the parametric design of bluff bodies on personal computers and devices. Overall, this method has a profound effect on design space exploration and the feedback control of separated flows. References: [1] D. E. Rumelhart, G. E. Hinton, and R. J. Construction of Basis Functions for Algebraic Dual Space

Varun Jain*, Yi Zhang**, Artur Palha***, Marc Gerritsma****

*Delft University of Technology, **Delft University of Technology, ***Eindhoven University of Technology, ****Delft University of Technology

ABSTRACT

In this work we develop a discretization method that explicitly uses functions from the algebraic dual space. Duality pairing between functions from the primal space and the dual space can be done in terms of the degrees of freedom only and do not (directly) depend on the basis functions, [2]. First, we prove the duality of these basis functions using the two examples from [1]. We prove the equivalence at discrete level between i) a pair of Dirichlet-Neumann problem in H(div, K), and ii) a pair of Dirichlet-Neumann problem in H(curl, K). We corroborate these proofs with numerical tests. Second, we demonstrate the application of these basis functions for two model constraint problems: i) scalar Laplacian, and ii) vector Laplacian. In both the applications we observe that the discretization of the constraint eq. is purely topological and is independent of grid shape and grid size. The corresponding matrix block consists of 1, -1 and 0 only, and is extremely sparse. Consequently, the condition number for the system is very low. The method is inf-sup stable. The error shows exponential convergence for both the applications. [1] C. Carstensen, L. Demkowicz, J. Taking into Account Thermal Constraints in Topology Optimization of Structures Built by Additive Manufacturing

Lukas Jakabcin*, Grégoire Allaire**

*Ecole Polytechnique, France, **Ecole Polytechnique, France

ABSTRACT

In this talk, we introduce a model and several constraints for shape and topology optimization of structures, built by additive manufacturing techniques. The goal of these constraints is to take into account the thermal residual stresses or the thermal deformations, generated by processes like Selective Laser Melting, right from the beginning of the structural design optimization. In other words, the structure is optimized concurrently for its final use and for its behavior during the layer by layer production process. It is well known that metallic additive manufacturing generates very high temperatures and heat fluxes, which in turn yield thermal deformations that may prevent the coating of a new powder layer, or thermal residual stresses that may hinder the mechanical properties of the final design. Our proposed constraints are targeted to avoid these undesired effects. Shape derivatives are computed by an adjoint method and are incorporated into a level set numerical optimization algorithm. Several 2-d and 3-d numerical examples demonstrate the interest and effectiveness of our approach. References: G. Allaire, L. Jakabcin,Taking into account thermal residual stresses in topology optimization of structures built by additive manufacturing, submitted. HAL preprint: hal-01666081 (2017).

ABSTRACT

Hydraulic fracturing is a widely used technology to stimulate tight and unconventional reservoirs and increase their ultimate recovery. Fractures are propagated in the rock matrix to create a fracture network and enhance the flow of hydrocarbons from the reservoir into the wellbore. The numerical simulation of hydraulic fracturing involves multiple multiphysics phenomena including: (1) fractures propagation, (2) fluid flow in the fractures and the reservoir, and (3) the accompanying mechanical deformations. Various computational models have been developed to simulate these coupled processes, yet many hydraulic fracture models focus on the near wellbore effects and fail to represent the holistic reservoir behavior. In this work, we develop a numerical framework to integrate non-planar fractures in large scale reservoir simulator (IPARS). The fracture permeability and geometry are obtained using the phase field fracture propagation method (IPACS). Fractures are then represented in the reservoir as small subdomains with high permeability coupled to the surrounding permeable formation. This configuration allows the simulation of the fluid flow in the reservoir and the fractures, yet restricts the time step. This means that fractured reservoir on the scale of kilometers would need to have its time steps governed by flow through fractures with apertures on the scale of millimeters. A space-time discretization is thus adopted, where the spatial domain is decomposed into overlapping or non-overlapping subdomains and a space-time variational formulation is employed. The flow in the reservoir is discretized using an Enhanced Velocity Mixed Finite Element Method. EVFEM adds additional velocity degrees of freedom on non-matching special and temporal interfaces to ensure the continuity of the flux. Numerical results are presented to show the impact of the induced fractures on the overall reservoir productivity.

Numerical and Experimental Investigation on Fracture Characteristics of Multilayer Graphene

Bongkyun Jang*, Byungwoon Kim**, Jae-Hyun Kim***, Hak-Joo Lee****

*Korea Institute of Machinery and Materials, **Korea Institute of Machinery and Materials, ***Korea Institute of Machinery and Materials, ****Korea Institute of Machinery and Materials

ABSTRACT

Graphene is 2-dimensional carbon layer with sp2-bondings like carbon nanotube and fullerene, and shows outstanding electrical, thermal, optical, and mechanical properties. Its excellent physical properties have been utilized for the various applications such as transparent conductor and, high-performance energy harvester and storage. Among them, extraordinary mechanical properties of graphene attract the attention to many fundamental researchers [1]. For fracture behavior of single crystalline and polycrystalline graphene, several experimental and analytical researches are performed, until now [2]. However, fracture mechanisms of multilayer graphene have not been fully studied, yet. In this study, we investigated fracture characteristics of multilayer graphene with experimental and numerical methods. For the fracture experiments, multilayer graphene specimens are fabricated by mechanical exfoliation from natural graphite and transferred onto tensile jigs, which can realize precise alignment and accurate application of loads to the specimens. In addition, narrow notches are fabricated with focused ion beam on the edges of the graphene specimens. Using these specimens, in situ fracture tests are performed under the scanning electron microscope. Load-displacement curves measured in the fracture experiments, and fracture load is obtained for each fracture specimen. Under the consideration of the shapes of the fracture specimens, we construct finite element models. By comparing the experimental results and the load-displacement curves calculated by finite element analyses, Young’s modulus of multilayer graphene is estimated. In addition, the stress distribution near the crack tip of the specimen can be calculated by the analysis. At the failure load, singular stress fields near the crack tip imply the intensified stress at the crack propagation, and the fracture toughness can be derived from them. Based on the experiments and finite element analysis, the fracture toughness of multilayer graphene is enhanced compared to the monolayer. From in situ observation of the fracture surface, interlayer slippages occur near the crack tip and fracture surface at the fracture. To elucidate the fracture mechanisms of multilayer graphene, molecular dynamics simulation is performed on the multilayer graphene specimens with single edge crack. The numerical simulation helps to explain how the fracture of multilayer graphene occurs when a uniaxial load applied. The experimental and numerical research on fracture of multilayer graphene can contribute to developing graphene-based electronic devices, and enhance the reliability of them. Topology Optimization for Three-dimensional Ultrasonic Acoustic Lens Design

Gang-Won Jang*, Quang Dat Tran**

*Sejong University, Republic of Korea, **Sejong University, Republic of Korea

ABSTRACT

For topology optimization of acoustic problems, the use of the finite element method (FEM) is limited to low or mid frequency applications because of considerable computational efforts especially in three-dimensional problems. To resolve this, a new method for efficiently solving topology optimization of high-frequency ultrasonic acoustic problems is proposed by combining the edge-based smoothed finite element method (ES-FEM) [1] and the wave based method (WBM) [2]. The ES-FEM is formulated by incorporating the gradient smoothing techniques of mesh free methods into the FEM. The ES-FEM is very suitable for acoustic problems due to the proper softening effect provided by the edge-based gradient smoothing operation. Because a close-to-exact stiffness of the system can be obtained in the ES-FEM, the dispersion error can be effectively suppressed in high frequency problems. Meanwhile, the WBM can give very accurate solutions with small number of degrees of freedom when applied to problems with simple geometries because it employs exact solutions of the governing equation as field variables. Through the hybrid use of the ES-FEM and WBM, great efficiency in the reduction of computational effort for high-frequency acoustic problems can be expected while retaining high analysis accuracy. The primary objective of this study is to develop shape and topology optimization of high-frequency acoustic problems based on the combined use of the ES-FEM and WBM. In the present paper, the entire domain is separated into design and non-design domains; the ES-FEM is applied to the design domain while the WBM is applied to the non-design domain. The interface tracking phase field approach in [3] is employed to implicitly parameterize the boundaries of acoustic lenses, which move according to design sensitivities during optimization. The effectiveness of the proposed hybrid method of the ES-FEM and WBM is verified by solving three-dimensional acoustic topology optimization problems with high frequency range (0.5-1MHz). Linear Smoothed eXtended Finite Element Method for Hyperelastic Materials

Chintan Jansari*, Sundararajan Natarajan**, Krishna Kannan***

*Indian Institute of Technology Madras, **Indian Institute of Technology Madras, ***Indian Institute of Technology Madras

ABSTRACT

In this talk, we propose the Linear Smoothed eXtended Finite Element Method for large deformation problems of hyperelasticity, with material interfaces in plane strain approximation. The eXtended Finite Element Method (XFEM) allows for the interior discontinuities to be represented independent of the underlying discretization. This is done by augmenting the conventional approximation space with suitable ansatz that carries the information of the local behaviour. However, this leads to difficulties in the numerical integration of the weak form and poor convergence properties due to the blending elements. The difficulty with the numerical integration is alleviated by employing the strain smoothing technique. And the stable XFEM is used to suppress the blending issues. Some numerical examples are solved and verified with the conventional FEM based on conforming mesh.

ABSTRACT

Parallel computing now delivers simulations in a time scale that could change the paradigm of how scientists, engineers, and other practitioners address discovery and design questions. Tools have been developed to precisely define a specific, complex simulation which can then be executed in seconds on computers. However, for discovery and design questions where the next variant of the problem requires change to the problem definition, the time to redefine the problem takes much longer. This delay interrupts intuition and learning about how the change in problem definition relates to a change in solution. To realize this innovative paradigm shift, referred to here as immersive simulation, requires the development of new approaches to problem definition editing that allow practitioners to interact with the simulations (visual model iteration) in a manner where they can dynamically experience (via in situ visualization that employs massive data reduction) the influence of parameter variations. In this talk we will describe our research efforts to advance state of the art tools into more generic components that, when integrated, will make the following capabilities available to any partial differential equation (PDE) solver: i) live, reconfigurable visualization of ongoing simulations, ii) live, reconfigurable problem definition to allow the dynamic solution insight to guide the choice of key problem parameters, iii) real-time parameter sensitivity feedback, iv) error estimation and adaptivity, and v) integration and demonstration of reliable, immersive simulation. This research will not only drive several of its science components in innovative and new directions, but, once integrated, will provide the field of simulation (and the science community that has developed an increasing dependence on it) with the ability to intuitively explore the behavior of the system. Furthermore, this research will allow interactively redefining the geometry, boundary conditions, and other parameters, to experience the science, and thereby greatly accelerate discovery and innovation.

Time-resolved Adaptive Direct FEM Simulation Prediction of Flow Separation

Johan Jansson*

*KTH Royal Institute of Technology

ABSTRACT

We present an adaptive finite element method for time-resolved simulation of aerodynamics without any turbulence model parameters, which is applied to a benchmark problem from the HiLiftPW-3 workshop to compute the flow past a JAXA Standard Model (JSM) aircraft model at realistic Reynolds number. The mesh is automatically constructed by the method as part of an adaptive algorithm based on a posteriori error estimation using adjoint techniques. No explicit turbulence model is used, and the effect of unresolved turbulent boundary layers is modeled by a simple parametrization of the wall shear stress in terms of a skin friction. In the case of very high Reynolds numbers we approximate the small skin friction by zero skin friction, corresponding to a free slip boundary condition, which results in a computational model without any model parameter to be tuned, and without the need for costly boundary layer resolution. We introduce a numerical tripping noise term to act as a seed for growth of perturbations, the results support that this triggers the correct physical separation at stall, and has no significant effect pre-stall. We show that the methodology quantitavely and qualitatively captures the main features of the JSM experiment - aerodynamic forces and the stall mechanism - with a much coarser mesh resolution and lower computational cost than the state of the art methods in the field, with convergence under mesh refinement by the adaptive method. Thus, the simulation methodology appears to be a possible answer to the challenge of reliably predicting turbulent-separated flows, for a complete air vehicle. We also present recent comparison against leading high-order frameworks in connection to the 5th International Workshop on High Order CFD Methods, showing that adaptivity and large timesteps enables high computational efficiency. The methodology is further extended to fluid-structure interaction with an embedded discontinuity in the phase interface by doubling the solution field, and we show a snapshot of the development. A Mixed Variational Framework for Structure-preserving Space-time Discretization for Non-linear Electro-elastodynamics

Alexander Janz*, Peter Betsch**, Marlon Franke***, Rogelio Ortigosa****

*Institute of Mechanics, Karlsruhe Institute of Technology (KIT), Germany, **Institute of Mechanics, Karlsruhe Institute of Technology (KIT), Germany, ***Institute of Mechanics, Karlsruhe Institute of Technology (KIT), Germany, ****Zienkiewicz Centre for Computational Engineering, Swansea University, Wales

ABSTRACT

The present talk deals with a new approach to the design of energy and momentum (EM) consistent integration schemes in the field of non-linear electro-elastodynamics, see Ortigosa, Franke, Janz, Gil and Betsch (submitted in Comput. Methods Appl. Mech. Engrg., 2017). The importance of electro-active polymers (EAPs) in different applications such as actors and sensors, soft robotics or artificial muscles requires advanced simulation techniques to prognosticate the behavior of such smart materials. Typically, these materials are described as electro-static but nevertheless the consistent time-integration of the electro-mechanical model plays an important role concerning the numerical stability and accuracy. In this talk we present a new approach to the design of energy-momentum consistent algorithms motivated by the structure of polyconvex stored energy functions and tailor-made for the consistent space-time discretization of EAPs. The presented time-integrator is based on the internal energy of the system, which is in accordance with the concept of polyconvexity for nonlinear electro-mechanics, see Gil and Ortigosa (Comput. Methods Appl. Mech. Engrg., 302: 293-328, 2016). Based on a Hu-Washizu-type mixed variational framework with a novel cascade form of kinematic constraints a new algorithmic stress formula is proposed, see Betsch, Janz and Hesch (accepted in Comput. Methods Appl. Mech. Engrg., 2017), which is a typical feature of energy-momentum methods. Furthermore, a tensor-cross product operator for second order tensors is used, which greatly simplifies the algebraic formulation. In addition, the time-discrete weak form of the Gauss's law and Faraday's law along with the concept of partitioned discrete derivatives leads to an implicit one-step time integrator which consistently approximates the linear momentum, the angular momentum as well as the total energy. The resulting structure-preserving integrator shows superior numerical stability and robustness compared to alternative formulations. Moreover, the mixed variational framework makes possible a wide variety of alternative finite element formulations. Along with an appropriate combination of the interpolation spaces high performance finite elements can be generated. Serval numerical examples dealing with large strains and electric fields are shown. These examples demonstrate the advantageous properties of the newly developed structure-preserving discretization scheme.

A Reliability Based Design Optimization Method for MASH TL-3 Concrete Barriers under Vehicle Crashes

Erica Jarosch*, Qian Wang**, Hongbing Fang***, Hangfeng Yin****

*Manhattan College, **Manhattan College, ***The University of North Carolina at Charlotte, ****Hunan University

ABSTRACT

Concrete barriers are commonly adopted on state highways to redirect impacting vehicles and reduce occupant injury risks. Due to the rigidity of a concrete barrier compared to other types of traffic barriers, its performance primarily depends on its cross-sectional shape. Besides physical crash tests, numerical simulations based on high-fidelity finite element (FE) analyses can be conducted to assess the performance of traffic barriers. This research work focused on the development of a reliability based design optimization (RBDO) method for concrete barriers subjected to vehicle impacts. The concrete barriers met the test level-3 (TL-3) requirements specified in the Manual for Assessing Safety Hardware (MASH). The proposed design optimization method started with nonlinear FE simulations at certain sample points so that crash responses could be used to evaluate barrier performance. A successive metamodeling technique developed using augmented radial basis functions (RBFs) was applied to create approximate functions of implicit crash responses. Once the RBF metamodels were created to approximate crash simulation results, the design constraints that included reliability calculations were evaluated using any sampling method such as Monte Carlo simulations (MCS). Finally, a genetic algorithm (GA) was adopted to optimize the objective function subjected to all the design constraints. The RBDO method integrated FE simulations, metamodels, MCS, and GA, and provided a useful tool for the design of roadside barriers. A concrete barrier example was solved and numerical results were presented to demonstrate the effectiveness of the design optimization method.

Error Estimation in Discontinuous Galerkin Method with Polygonal Finite Elements

Jan Jaskowiec*

*Cracow University of Technology, Institute for Computational Civil Engineering, Poland

ABSTRACT

In the paper three methods for error estimation in the two-dimensional (2D) discontinuous Galerkin method (DGM) are presented. The applied DGM version uses arbitrary polygonal finite elements [1,2]. The Chebyshev basis functions are used for approximation. They are constructed recursively which makes the method very efficient and flexible. It is then quite easy to calculate higher order derivatives of the basis functions on the polygonal finite elements. In the first error estimation method, the residual error from the strong form can be obtained directly from the approximate solution. The residual error is discontinuous, so the Zienkiewicz-Zhu smoothing procedure is employed for the continuous error distribution. In the DGM the recursive basis functions are utilized. In this case, it is very easy to obtain a low order solution of the considered problem in a situation when the higher order solution is already calculated. It is because the stiffness matrix has hierarchical construction, and so the lower order stiffness matrix is just a part of the primary stiffness matrix. In the second method, the error is estimated by comparison of two approximate solutions. The two solutions are of different orders and the lower-order solution is calculated with marginal cost. In the third method, a special boundary value problem (PVB) is constructed to estimate the error. The error PVB is obtained and solved with low computational costs due to some special properties of the DGM utilized in this method. The quality of the error estimation is very high in the last method. The paper is illustrated with two-dimensional benchmark examples where the standard scalar Poisson's boundary value problems are considered. In the examples the correctness and flexibility of the proposed error estimation methods are shown. The two-dimensional examples of linear elasticity are also presented, in which the errors are estimated in situations when stress concentrations occur in the final solution. [1] E. B. Chin, J. B. Higher Order Multipoint Meshless FDM for Two-scale Analysis of Heterogeneous Materials

Irena Jaworska*

*Cracow University of Technology

ABSTRACT

The paper focuses on application of the Multipoint solution approach – the higher order extension of the Meshless Finite Difference Method (MFDM) to the numerical homogenization of the heterogeneous material with periodic structure. The Finite Element Method (FEM) has been the most commonly applied method of computer modeling for the multiscale problem. However, this fact does not mean that one should not search for the alternative, perhaps more efficient approaches, especially based on the meshless technique which uses only a set of nodes for discretization of the continuum and therefore leads to greater flexibility. Recently developed Multipont meshless method is discussed here for this purpose. The higher order Multipont approach is followed the original Collatz [1] concept and the essential idea of the MFDM [2] – the moving weighted least squares approximation, using the arbitrarily irregular cloud of nodes as well as various formulations of b.v. problem. The higher order approximation, applied in the Multipoint method, is based on the additional degrees of freedom at all stencil nodes, taking into account e.g. the right hand side of considered differential equation. It improves obtained solution without necessity of providing additional unknowns to both – the mesh and the MFD operator, and also may be used e.g. for high quality a posteriori error estimation of the results. The higher order Multipont meshless method, like the MFDM solution approach [3], may be used at both – the macro and the micro levels in the two-scale analysis of heterogeneous materials based on the single RVE. The analysis of the convergence results of the effective material parameters for the set of meshes with increasing number of nodes as well as comparison with FEM was conducted. The error analysis done at the micro level confirm the high quality of the Multipoint solution, which may be used as the improved reference solution instead of the true analytical one for the a posteriori error estimation. Key words: Random heterogenous material; Inelastic cyclic behavior; Uncertainty quantification; Global sensitivity analysis; Variance decomposition.

Abstract. *The uncertainty and the sensitivity of the response of a nonlinear stochastic multi-scale numerical model for randomly heterogenous material is investigated. 9 input parameters and 10 descriptors of the time-dependent output response are considered. The material model has been presented elsewhere and is introduced as a 'black box function' in the present paper, parameterized so that the model is deterministic and that variability in the outputs only comes from the variability introduced in the inputs. The objective is twofolds: (i) surveying the variety of macroscopic behaviors the material model considered is capable of representing, and (ii) assessing the relative importance of the model inputs in the model outputs to, for instance, define efficient parameters identification protocoles. A preliminary analysis of the linear dependency between the output descriptors is presented and a reduced set of 6 descriptors is eventually selected. Then, the influence of the model input parameters on each of these model response descriptors is investigated using a global sensitivity analysis technique based on the functional decomposition of their respective total variance.*

1 INTRODUCTION

The mechanical behavior of a wide range of natural or manufactured materials is characterized by macroscopic engineering parameters that depend on phenomena at heterogeneous smaller scales (concrete, nano-engineered materials [12]). On the one hand, experimental devices and techniques allow characterizing the spatial distribution of material properties at micro-scales as for instance the combination of atomic force microscope imaging and quantitative nanomechanical property mapping techniques employed in [14] for a study of Young's modulus distribution in the so-called interfacial transition zone in concrete material. On the other hand, computational material models allow carrying out numerical experiments that have the potential of investigating the material behavior in a range of configurations that can be difficult to reach with sole experimental investigation. There is therefore a need for developing such numerical material models that can simulate engineering properties at macro-scale from relevant

information coming from lower scales. This has been a topic of continuing research in the field of computational mechanics for decades.

The development of the inelastic stochastic multi-scale numerical model investigated in the present work (see [5] and [6]) was initially motivated by the need for a concrete model that is capable of representing the contribution of material damping to the overall structural damping in the seismic analysis of civil engineering assets. In earthquake engineering, structural damping is indeed commonly introduced in numerical simulations using ad hoc damping models such as the pervasive so-called Rayleigh damping model. Unfortunately, as nonlinear structural analysis is performed, resorting to such ad hoc approach potentially results in large uncertainties when assessing structural seismic performance.

This concrete model [5, 6] is based on a meso-scale where the heterogeneous structure is represented by random vector fields. Local behavior at meso-scale is nonlinear and can be seen as the homogenized response of other mechanisms at lower scales when explicit construction of smaller scales is not possible. The model is constructed with a set of parameters that describes the structure of the random vector fields (correlation coefficients, correlation lengths and functions); a set of parameters that characterizes the mean, variance and distribution of physical parameters at meso-scale (initial stiffness, yield stress and stiffness degradation ratio); and a set of parameters for spatial discretization of the material domain (finite element method) and of the random fields (spectral representation method [11]). A representative volume element (RVE) can be retrieved with the ability to represent salient features of the concrete uniaxial cyclic compressive response that are not explicitly represented at meso-scale, like for instance the hysteresis loops experimentally observed in unloading-reloading cycles.

The objective of this paper is twofolds: (i) surveying the variety of macroscopic behaviors this numerical inelastic stochastic multi-scale material model is capable of representing, and (ii) assessing the relative importance of the model inputs in the model outputs to, for instance, define efficient parameters identification protocoles. Next section is focussed on introducing the model input parameters. Then, a probabilistic framework is set in section 3 for uncertainty and global sensitivity analysis. In section 4, the results of an application are presented and, finally, a list of conclusions closes the paper.

2 THE MATERIAL MODEL AND ITS INPUT PARAMETERS

The material model used in this paper has been developed to represent the restoring force $f(t)$ of a 1D nonlinear material in a given cyclic quasi-static loading displacement time history $u(t)$ where t is the pseudo-time (Fig. 1). This material model is referred to as $\mathcal{M}$, it takes t along with a set of parameters $\mathbf{x}$ as inputs, and yields the restoring force history $f(t)$ as output.

Figure 1: The experiment: bar with quasi-static displacement $u(t)$ imposed at one end, with other end fixed where reaction $f(t)$ develops; it is assumed that the experiment is such that the strain field is homogeneous in the bar.

The material model $\mathcal{M}$ that is used in this work has been presented in [5, 6]. Therefore, we only introduce here its main characteristics along with the list of input parameters that will be used for uncertainty and sensitivity analyses hereafter. Also, for the sake of illustrating, we

consider that the modeled material is concrete; but any other random heterogeneous material described by 3 scales as introduced in Tab. 1 and Fig. 2 could fit this setting.

Scale	Observations	Modeling assumptions
Micro	Physical and chemical mechanisms occur	Internal variables are considered in the framework of continuum thermodynamics [1, 8] to convey information from this scale to the meso-scale (see Fig. 3).
Meso	Aggregates and the cement paste are observable and build an heterogenous material structure	The heterogeneity at this scale is represented using random fields rather than an explicit representation of the structure.
Macro	Homogeneous quantities are retrieved for engineering purposes	Classical homogenization technique in the framework of the Finite Element Method is used [9, 10].

Table 1: The 3 scales introduced in the model $\mathcal{M}$. Concrete material is considered here as an illustrating example.

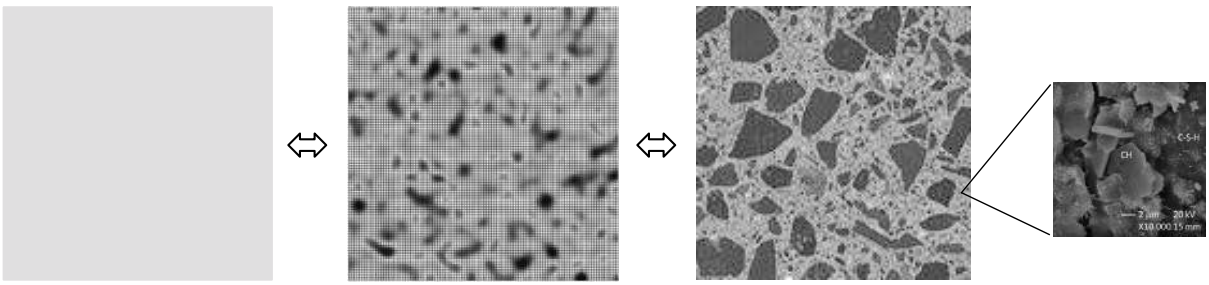

Figure 2: From left to right: [a] equivalent homogeneous concrete (macro-scale), [b] representation of the heterogeneous concrete at meso-scale (5 cm $\times$ 5 cm-square), [c] actual heterogeneous concrete (5 cm $\times$ 5 cm-square), and [d] zoom on the underlying microstructure in the cement paste (20 μm $\times$ 20 μm-square observed through Scanning Electron Microscope, courtesy A.P.M. Trigo [13]).

The model uses stochastic fields to represent spatial variations – that is random heterogeneity – in the material properties at meso-scale. The actual meso-scale shown in Fig. 2[c] is replaced by random vector fields as shown in Fig. 2[b]. In the particular case of a 1D material behavior, which this work is limited to, three parameters are represented as spatially variable as illustrated in Fig. 3: the initial stiffness $C(\mathbf{p}, \omega)$ (or Young's modulus at meso-scale), the yield stress $\sigma_y(\mathbf{p}, \omega)$, and the stiffness degradation ratio $r(\mathbf{p}, \omega) \in [0, 1]$, where $\mathbf{p}$ is a position in the material and ω recalls the randomness in the quantity. The three quantities are correlated and the same correlation coefficient ρ is considered for any pair of parameters. The parameters $\mathbf{x}$ of model $\mathcal{M}$ are listed in Tab. 2.

The model $\mathcal{M}$ can be stochastic: same input parameters $\mathbf{x}$ and imposed displacement history $u(t)$ can yield different outputs. Nevertheless, it has been shown in [5, 6] that the model can also be deterministic: same input parameters $\mathbf{x}$ and loading history $u(t)$ would yield same output. In other words, it is possible to parameter the model in such a way that a material Representative Volume Element (RVE) is simulated. This can be achieved using particular set of spatial parameters ($N = 16$, $M = 32$, $M_f = 96$, $L_0/\ell = 0.1$, $\epsilon_R = 0.01$ using the same notations as in [5]). This parameterization is used in this paper so that uncertainty observed in the output parameters $\mathbf{y}$ would only come from uncertain input parameters $\mathbf{x}$.

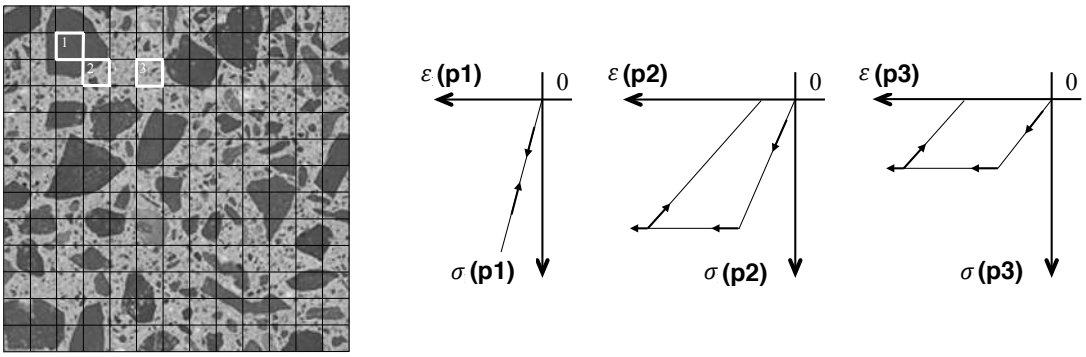

Figure 3: Behavior law at meso-scale depends on the position $\mathbf{p}$ in the heterogeneous material. Initial stiffness, yield stress, and stiffness degradation ratio at any point $\mathbf{p}$ are modeled as random variables.

$\mathbf{x}$	Description
$x_1 = law_C$	Initial stiffness C distribution (log-normal or uniform)
$x_2 = a_C$	Mean of law_C
$x_3 = b_C$	Variance of law_C
$x_4 = law_{\sigma_y}$	Yield stress σ_y distribution (log-normal or uniform)
$x_5 = a_{\sigma_y}$	Mean of law_{σ_y}
$x_6 = b_{\sigma_y}$	Variance of law_{σ_y}
$x_7 = a_r$	Mean of the stiffness degradation ratio uniform distribution law_r
$x_8 = b_r$	Variance of law_r
$x_9 = \rho$	Correlation coefficient between (C and σ_y), (C and r), or (σ_y and r)

Table 2: List of the $N^x = 9$ model input parameters x_j, $j = 1 \dots N^x$ considered in this work.

3 UNCERTAINTY AND SENSITIVITY ANALYSES OF THE MODEL OUTPUT

Let introduce the probability space $(\Theta, \mathcal{S}, P)$ with sample space Θ, collection of events $\mathcal{S}$, and probability measure P. To introduce a certain degree of belief in the set $\mathbf{x}$ of the model input parameters, we consider them as random variables $\mathbf{X} : \theta \in \Theta \mapsto \mathbf{X}(\theta)$. Consequently, the model output $f(t)$ also is a random variable $F(t) : \theta \mapsto F(t, \theta)$ for all $t \in [0, T]$ and we have the deterministic model $\mathcal{M}$ that is the mapping

$$\mathcal{M} : (\theta, t) \mapsto F(t) = \mathcal{M}(\mathbf{X}, t) \tag{1}$$

3.1 Uncertainty analysis

The uncertainty in the model output can be analyzed computing quantities such as the mean, variance, and cumulated density function for all $t \in [0, T]$:

$$E[F(t)] = \int_\Theta \mathcal{M}(\mathbf{X}(\theta), t)\, dP(\theta) \tag{2}$$

$$V[F(t)] = \int_\Theta \big(E[F(t)] - \mathcal{M}(\mathbf{X}(\theta), t)\big)^2\, dP(\theta) \tag{3}$$

$$\Pr[F(t) \leq f(t)] = \int_\Theta \delta_{f(t)}[\mathcal{M}(\mathbf{X}(\theta), t)]\, dP(\theta) \quad \text{with} \quad \delta_{f(t)}[\cdot] = \begin{cases} 1 & \text{if } \cdot \leq f(t) \\ 0 & \text{if } \cdot > f(t) \end{cases} \tag{4}$$

This requires computing integrals over the sample space Θ. To this purpose, Monte Carlo simulations are performed from a Latin hypercube sample (LHS) of size N^s. LHS is adopted here for its efficiency compared to random sampling [3, 7] with the N^x input random variables in $\mathbf{X}$ assumed as mutually independent.

3.2 Sensitivity analysis

For the analysis of the sensitivity of the model output to the inputs, the approach adopted in this work is based on a functional decomposition of the variance (see e.g. [4]), $\forall t \in [0, T]$, as:

$$V[F(t)] = \sum_{j=1}^{N^x} D_j[F(t)] + \sum_{1 \leq j < k \leq N^x} D_{jk}[F(t)] + \ldots + D_{12\ldots N^x}[F(t)] \tag{5}$$

where $D_j[F(t)] = V\left[E[F(t)|X_j]\right]$, $D_{jk}[F(t)] = V\left[E[F(t)|X_j, X_k]\right] - D_j[F(t)] - D_k[F(t)]$ and so on. Then, the following first-order and total indices are computed from $(N^x + 2) \times N^s$ computations of the model response as:

$$s_j = \frac{D_j[F(t)]}{V[F(t)]} \tag{6}$$

$$s_{jT} = s_j + \frac{\sum_{k=1, k\neq j}^{N^x} D_{jk} + \sum_{1 \leq k \neq j < l \neq j}^{N^x} D_{jkl} + \ldots + D_{12\ldots N^x}}{V[F(t)]} \tag{7}$$

where s_j, respectively s_{jT}, is the portion of $V[F(t)]$ due to input x_j alone, respectively to x_j and all the interactions of x_j with the other input variables.

4 APPLICATION

4.1 Uncertainty in the model input parameters

The distributions selected for the uncertain input parameters are introduced in Tab. 3.

$\mathbf{X}(\theta)$	Distribution: $law(mean, variance)$	
$X_1 = LAW_C$	$\mathcal{B}_{0.5}$: either $\mathcal{U}(a_C, b_C)$ or $\mathcal{L}(a_C, b_C)$	with probability 0.5 each
$X_2 = A_C$ [MPa]	$\mathcal{U}(\tilde{a}_C = 30e3, 0.04\,\tilde{a}_C^2)$	such that $C \geq 0$
$X_3 = B_C$ [MPa^2]	$\mathcal{U}(\tilde{b}_C = 15e3, 0.04\,\tilde{b}_C^2)$	such that $C \geq 0$
$X_4 = LAW_{\sigma_y}$	$\mathcal{B}_{0.5}$: either $\mathcal{U}(a_{\sigma_y}, b_{\sigma_y})$ or $\mathcal{L}(a_{\sigma_y}, b_{\sigma_y})$	with probability 0.5 each
$X_5 = A_{\sigma_y}$ [MPa]	$\mathcal{U}(\tilde{a}_{\sigma_y} = 35, 0.04\,\tilde{a}_{\sigma_y}^2)$	such that $\sigma_y \geq 0$
$X_6 = B_{\sigma_y}$ [MPa^2]	$\mathcal{U}(\tilde{b}_{\sigma_y} = 20, 0.04\,\tilde{b}_{\sigma_y}^2)$	such that $\sigma_y \geq 0$
$X_7 = A_r$	$\mathcal{U}(\tilde{a}_r = 0.5, 0.04\,\tilde{a}_r^2)$	such that $r \in [0, 1]$
$X_8 = B_r$	$\mathcal{U}(\tilde{b}_r = 0.02, 0.04\,\tilde{b}_r^2)$	such that $r \in [0, 1]$
$X_9 = Rho$	$\mathcal{U}(0.5, 1/12)$	(support is $[0, 1]$)

Table 3: Random variables and there distributions characterized by their mean and variance. $\mathcal{B}$, $\mathcal{U}$, and $\mathcal{L}$ are Bernoulli, uniform, and log-normal distributions. How to find the support of a uniform distribution from its mean and variance is shown in the Annex. Quantities with superimposed tilde $\tilde{\cdot}$ are some nominal mean values; a coefficient of variation of 20% is considered to calculate the variance associated to these nominal mean values.

4.2 Model response descriptors

We start by simulating the material response in one symmetric loading cycle with macroscopic strain amplitude $E = 3.5e^{-3}$. $N^s = 500$ simulations are run and model responses are plot in Fig. 4. From the observation of this figure we choose a series of N^y model response descriptors as introduced in Fig. 5, gathered in vector $\mathbf{y}$. Then, we seek possible linear dependencies – other types of dependencies could of course be sought too – and build Fig. 6. From Fig. 6, it is observed that model response after point D is strongly correlated to model response between points O and D. Accordingly, only the following $N^y = 6$ model response descriptors will be considered thereafter: $y_1 = C_O$, $y_2 = C_B$, $y_3 = \Sigma_A$, $y_4 = \Sigma_B$, $y_5 = \Sigma_D$, and $y_6 = E_C$.

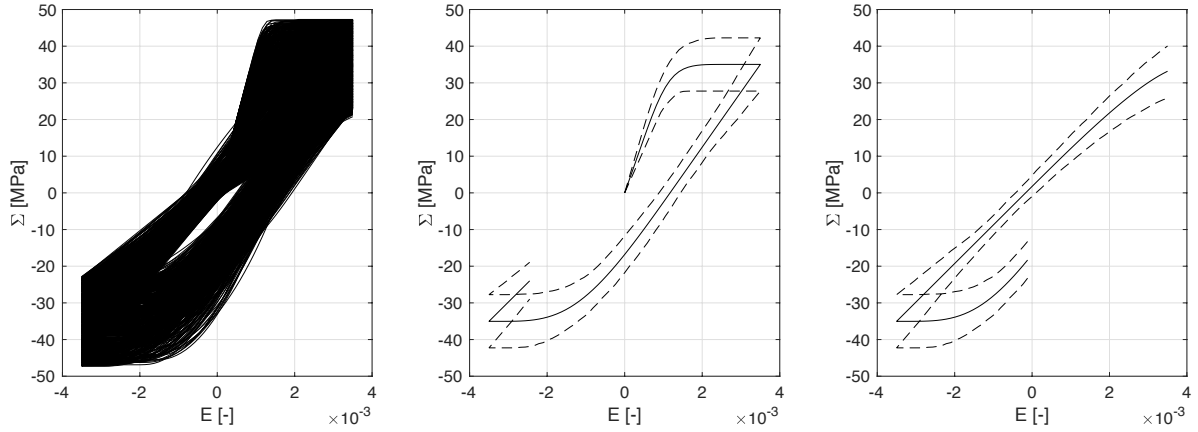

Figure 4: [left] $N^s = 500$ model response curves. [middle] and [left] Sample mean along with the 10% and 90% percentiles (dashed line); response curves are split into two parts for better readability.

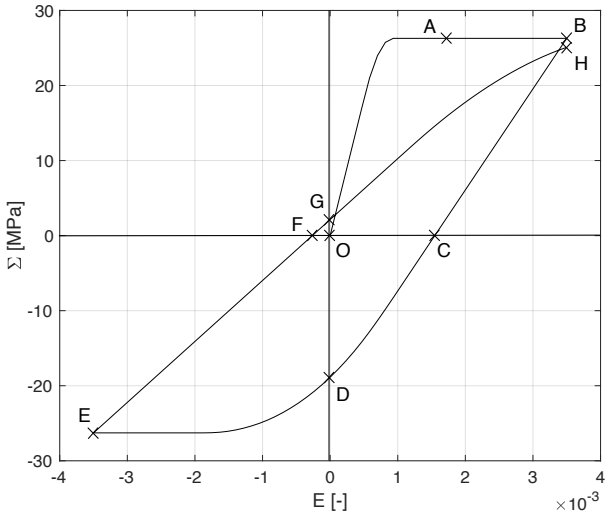

Figure 5: Model response descriptors: initial tangent modulus C_O and unloading tangent modulus at point B C_B; stresses Σ_A ($E = 1.75e^{-3}$), Σ_B, Σ_D, Σ_E, Σ_G, and Σ_H; strains E_C and E_F.

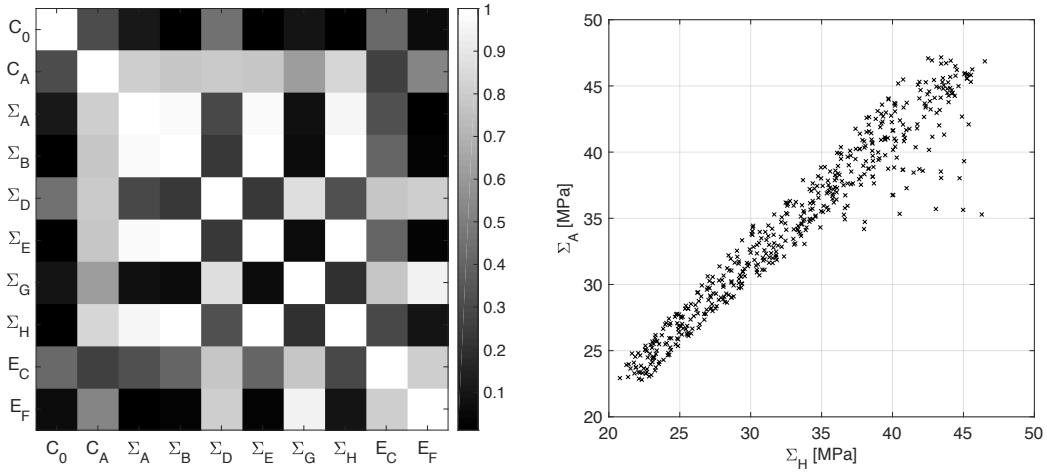

Figure 6: [left] Absolute value of the sample Pearson correlation coefficients between model response descriptors y_k, $k = 1 \dots N^y$; [right] scatterplot of Σ_A versus Σ_H showing strong linear correlation.

4.3 Uncertainty and sensitivity estimators

To estimate global sensitivity of the model outputs $\mathbf{y}$ to the inputs $\mathbf{x}$, the method detailed in [2] (Sect. 6.13) has been implemented. Accordingly:

1. A first LHS $[x_{ij}]$, $i \in [0, N^s]$ and $j \in [0, N^x]$, is generated and the model response $\mathbf{y}_i(t) = \mathcal{M}(\mathbf{x}_i, t)$ is computed for each set of input parameters $\mathbf{x}_i = [x_{i1} \cdots x_{iN^x}]$. From these quantities, estimators of the mean and variance in Eqs. (2) and (3) are computed $\forall k \in [1 \dots N^y]$ as:

$$\hat{E}[Y_k] = \frac{1}{N^s} \sum_{i=1}^{N^s} y_{k,i}(t) \quad ; \quad \hat{V}[Y_k] = \left(\hat{\sigma}[Y_k]\right)^2 = \frac{1}{N^s} \sum_{i=1}^{N^s} \left(\hat{E}[Y_k] - y_{k,i}(t)\right)^2 \tag{8}$$

2. Another sample $[\bar{x}_{I,j}] = [p(\mathbf{x}_1) \cdots p(\mathbf{x}_{N^x})]$, $I \in [0, N^s]$, is built, where $p(\mathbf{x}_j)$ is a random permutation without replacement of the N^s elements of the j-th column of $[x_{ij}]$. The model response $\bar{\mathbf{y}}_I(t) = \mathcal{M}(\bar{\mathbf{x}}_I, t)$ is computed for each $\bar{\mathbf{x}}_I = [\bar{x}_{I1} \cdots \bar{x}_{IN^x}]$. Then, N^x samples of N^s model responses are obtained by reordering the computed $\bar{\mathbf{y}}_I(t)$'s as follows: $\bar{\mathbf{y}}_i^{(j)}(t) = \mathcal{M}([\bar{x}_{I1} \cdots \bar{x}_{Ij} = x_{ij} \cdots \bar{x}_{IN^x}], t)$, $j \in [0, N^x]$.

3. A last LHS $[\check{x}_{ij}]$, $i \in [0, N^s]$ and $j \in [0, N^x]$, is generated and N^x samples of N^s model responses are computed as $\bar{\bar{\mathbf{y}}}_i^{(j)} = \mathcal{M}(\bar{\bar{\mathbf{x}}}_i^{(j)}, t)$, $\bar{\bar{\mathbf{x}}}_i^{(j)} = [\bar{\bar{x}}_{i1}^{(j)} \cdots \bar{\bar{x}}_{iN^x}^{(j)}]$, with $\bar{\bar{x}}_{iJ}^{(j)} = x_{iJ}$ for $J \in [0, N^x]$ except for $J = j$ where $\bar{\bar{x}}_{iJ}^{(j)} = \check{x}_{ij}$.

Estimators for the sensitivity indices are then computed, $\forall k \in [1 \dots N^y]$, as:

$$\hat{s}_{k,j} = \frac{1}{\hat{V}[Y_k]} \left(\frac{1}{N^s} \sum_{i=1}^{N^s} y_{k,i}(t) \times \bar{y}_{k,i}^{(j)}(t) - \hat{E}[Y_k]^2 \right) \tag{9}$$

$$\hat{s}_{k,jT} = \frac{1}{N^s \times \hat{V}[Y_k]} \sum_{i=1}^{N^s} y_{k,i} \left(y_{k,i} - \bar{\bar{y}}_{k,i}^{(j)} \right) \tag{10}$$

Altogether, the model has to be run $(2 + N^x) \times N^s$ times. In the present work, $N^x = 9$, $N^s = 300$, 400, or $1,000$, and computing one model response takes less than 2 seconds. The calculated estimations are shown in Tab. 4.

	N^s	$y_1 = C_0$	$y_2 = C_B$	$y_3 = \Sigma_A$	$y_4 = \Sigma_B$	$y_5 = \Sigma_D$	$y_6 = E_C$

Table 4: Estimates $\hat{E}[Y_k]$ and $\hat{\sigma}[Y_k]$ for expected value and standard deviation of the model response descriptors y_k with $k = 1 \dots N^y$; estimates $\hat{s}_j$ for the contribution of each input x_j with $j = 1 \dots N^x$; estimates $\hat{s}_{jT}$ for the contribution of each input x_j and all its interactions with the other inputs x_p with $p = 1 \dots N^x$ and $p \neq j$.

5 CONCLUSIONS

In the particular case of the experiment shown in Fig. 1, and from the above presented work, the following conclusions can be drawn about the inelastic stochastic multi-scale numerical model for random heterogeneous materials developed in [5] and [6]:

- Fig. 4: The model simulates macroscopic behaviors of analogous shapes for all the sets of input parameters considered.
- Tab. 4: Clear trends regarding the relative importance of the model input parameters on the outputs can be observed with a relatively small number of simulations.
- Tab. 4: 3 out of 9 input parameters are key to control the simulated macroscopic response, namely the means of the random fields at meso-scale: a_C, a_{σ_y}, and a_r.
- Tab. 4: Combined actions of two or more input parameters on the model outputs are very limited ($\hat{s}_{k,j} \approx \hat{s}_{k,jT}$, $\forall (j,k) \in [1, N^x] \times [1, N^y]$).
- Tab. 4: Initial stiffness C_O at macro-scale solely depends on the mean a_C of the initial stiffness marginal distribution at meso-scale (see Fig. 4). This is in accordance with the way the model is built: by definition $C_O =< C(\mathbf{p}, \omega) >$ with $< C(\mathbf{p}, \omega) >$ the spatial mean of the initial stiffness field over the material RVE, and, consequently to ergodicity properties of the random vector field at meso-scale $a_C =< C(\mathbf{p}, \omega) >$; accordingly: $C_O = a_C$.

ANNEX - Support of a uniform distribution with know mean and variance

Let $\mathcal{U}(a,b)$ be a uniform distribution over the range $[x;y]$ $(x<y)$ with mean a and variance $b^2>0$. In this annex, we show how to calculate x and y from a and b. By definition, the following nonlinear system has to be solved:

$$\left\{\begin{array}{l} x+y=2a \\ (y-x)^2=12b^2 \end{array}\right. \tag{11}$$

Introducing $C^2=4a^2$ and $D^2=12b^2$, Eqs. (11) implies that:

$$\left\{\begin{array}{l} (x+y)^2=C^2 \\ (x-y)^2=D^2 \end{array}\right. \quad \Rightarrow \quad \left\{\begin{array}{l} x+y=\pm C \\ x-y=\pm D \end{array}\right. \tag{12}$$

Consequently, we have the following four possible couples of solutions:

$$\begin{array}{l} (x_1,y_1)=((C+D)/2\ ,\ (C-D)/2) \\ (x_2,y_2)=((C-D)/2\ ,\ (C+D)/2) \\ (x_3,y_3)=((-C+D)/2\ ,\ (-C-D)/2) \\ (x_4,y_4)=((-C-D)/2\ ,\ (-C+D)/2) \end{array} \tag{13}$$

From Eqs. (13), the following table can be built:

i	$(x_i+y_i)/2$	x_i-y_i	$(C,D)=$ $(2a,\sqrt{12}b)$	$(C,D)=$ $(2a,-\sqrt{12}b)$	$(C,D)=$ $(-2a,\sqrt{12}b)$	$(C,D)=$ $(-2a,-\sqrt{12}b)$
1	$C/2$	D	No	Yes	No	No
2	$C/2$	$-D$	Yes	No	No	No
3	$-C/2$	D	No	No	No	Yes
4	$-C/2$	$-D$	No	No	Yes	No

A *Yes* means that both conditions $(x_i+y_i)/2=a$ and $x_i<y_i$ are true for the corresponding values of C and D, while a *No* is indicated otherwise. Because there is always one and only one *Yes* for each value of i, this table shows the intuitive fact that x and y are uniquely determined from a and b. Besides, if for instance we consider that $(x,y)=(x_2,y_2)$ in Eqs. (13) with $C=2a$ and $D=\sqrt{12}b$ (corresponding to a Yes), we have:

$$x=a-\sqrt{3}b \qquad \text{and} \qquad y=a+\sqrt{3}b \tag{14}$$

As a direct application of Eqs. (14), it is for instance straightforward to guarantee that $[x,y]\subset[0,1]$ if, for any $a\in[0,1]$, b is calculated as

$$\left\{\begin{array}{l} a-\sqrt{3}b\geq 0 \\ a+\sqrt{3}b\leq 1 \end{array}\right. \quad\Rightarrow\quad b\leq min\left(a/\sqrt{3}\,;\,(1-a)/\sqrt{3}\right) \tag{15}$$

Acoustic Black Holes: from Generalization to Realization

Wonju Jeon*

*KAIST

ABSTRACT

This study starts with a simple question: can we efficiently reduce the vibration of plates or beams using a lightweight structure that occupies a small space? As an efficient technique to dampen vibration, we adopted the concept of an Acoustic Black Hole (ABH) with a simple modification of the geometry. The original shape of an ABH has a straight wedge-type profile with power-law thickness, with the reduction of vibration in beams or plates increasing as the length of the ABH increases. However, in real-world applications, there exists an upper bound of the length of an ABH due to space limitations. Therefore, in this study, the authors propose a curvilinear shaped ABH using the simple mathematical geometry of an Archimedean spiral, which allows a uniform gap distance between adjacent baselines of the spiral. In numerical simulations, the damping performance increases as the spiral length of the Archimedean spiral increases regardless of the curvature of the spiral in the mid- and high-frequency ranges. Adding the damping material to the ABH could strongly enhance the damping performance while not significantly increasing the weight. In addition, the authors experimentally investigate the effect of curvatures of the curved ABH on the vibration damping performance. The curved ABHs studied in this work are divided into two cases: (1) the curved ABH with the baseline of constant curvatures which has a circular arc shape, (2) the curved ABH with the baseline of varying curvatures. After manufacturing the spiral ABH with high precison, the authors perform experiments to investigate the effect of curvatures on the damping performance of the circular arc shaped ABHs. An Archimedean spiral ABH, a particular form of the curved ABH of slowly varying curvatures is also investigated experimentally in order to create the possibility of using the spiral ABH as a new and efficient method of damping vibration in real-world problems.

Identification of Elastic Moduli and Length Scale Parameter for Strain Gradient Theory from Full-field Measurements

ABSTRACT

Classical continuum solid mechanics have been widely used in various fields for decades, but cannot demonstrate some phenomena such as size effects and deformation of micro- and nano-scale structures. To overcome these limitations, many researchers have developed the strain gradient theory in which the classical theory is enriched by adding first derivatives of macroscopic strains, i.e. second derivatives of displacements, to the constitutive equations. Additional parameters called length scale parameters need to be introduced for the higher order terms and it is necessary to experimentally measure the exact value of the parameters for the practical application of the strain gradient theory. Recent advances in optical devices and image processing have led to the development of methodologies such as digital image correlation which can measure full-field displacements of structures. Full-field measurements make it possible to identify more accurate and realistic material parameters compared to the traditional method especially when the stresses and strains are not uniform. Furthermore, identification methods based on full-field measurement can extract the parameters from a relatively small number of experiments even though the material has heterogeneous or nonlinear constitutive properties. In this research, constitutive parameters for gradient elasticity including length scale parameter are identified from full-field displacements by minimizing the gap between measured and numerical quantities. For the numerical analysis, finite element method with staggered gradient elasticity based on Ru-Aifantis theorem is used since it only need C0-continuous interpolation functions. Finite element analysis of the strain gradient theory basically requires C1-continuity due to the higher order terms, but staggered gradient elasticity divides the solution process into two step so that C0 elements suffice. The accuracy and robustness of the proposed method are verified in a couple of numerical examples. Calculation of Surface Energy Barriers of Droplet Adhesion to Textured Solid Surface in Cassie-Baxter Wetting Mode by Using Numerical Modeling

Minsoo Jeong*, Seunghwa Ryu**, Keonwook Kang***

*Department of Mechanical Engineering, Yonsei University, Republic of Korea, **Department of Mechanical Engineering, KAIST, Republic of Korea, ***Department of Mechanical Engineering, Yonsei University, Republic of Korea

ABSTRACT

The phenomenon that particles stick to the solid surface is called particle surface adhesion. The wettability of a particle on the surface can be tuned by changing the topology of the surface. In this work, we developed a line tension model to understand the surface adhesion phenomenon of a deformable body to solid surface. Our model is validated by comparing with analytical solutions of D. Kim et al.(2016)[1] and Young et al.(1805)[2] which calculate the surface energy and contact angle of water droplet adhered to the solid surface in Cassie-Baxter wetting mode. The model produces consistent result that the wettability of the patterned solid surface is lower than that of flat surface. Besides, the unrealistic non-smooth droplet shape is avoided in our numerical modeling. In addition, the surface energy barriers that are generated when the contact angle changes in the Cassie-Baxter wetting mode are calculated. High Fidelity Modeling and Simulation of Earthquake Soil Structure Interaction Effects for Infrastructure Objects

Boris Jeremic*, Yuan Feng**, Han Yang***, Hexiang Wang****, Francis McKenna*****, David McCallen******

*UCD, LBNL, **UCD, ***UCD, ****UCD, *****LBNL, ******LBNL

ABSTRACT

Interaction of dynamics of three components: (1) an earthquake, (2) soil/rock and (3) the structure, control the response of structures during earthquakes. It is postulated that this interaction, called Earthquake Soil Structure Interaction (ESSI) can sometimes be beneficial and sometimes detrimental to dynamic response of infrastructure objects. Accurate modeling of ESSI effects is possible when modeling uncertainties, that are introduced in results when modeling simplifications are made, are controlled and that their influence on results is known. A hierarchy of models, from simpler toward more sophisticated, is used to estimate influence of modeling uncertainties. Higher modeling sophistication models require high performance computing (HPC) approach to simulations. Presented here is our approach to modeling ESSI effects for dynamic behavior of buildings and other safety related structures (bridges, dams, etc.). Approach is based on a notion of availability of a hierarchy of modeling and simulation tools, from low to high fidelity, that allow for deterministic and probabilistic models to be used in the analysis. Effects of modeling simplifications on ESSI modeling and simulation results are tested through the use of multiple levels of sophistication for models, from simple 1D elastic stick models, to sophisticated 3D inelastic solid, contact, shell, beam models. In addition, accurate following of seismic energy, as it propagates through the soil structure system, is used to improve safety and economy of infrastructure objects. HPC approach to medaling and simulation of ESSI effects is presented on both fine and coarse grained levels. Fine grain level HPC is based on application of Small Linear Algebra (SLA) to tensor computations on the constitutive and finite element level. Coarse grained level HPC is based on massively parallel computations using Ring Buffer (RB) dynamic load balancing that is applicable to local clusters, to Cloud Computing (Amazon Web Services (AWS) for example) as well as to large national supercomputers (EDISON and CORI at LBNL for example). A number of examples will illustrate aspects of modeling and simulation of ESSI behavior using HPC approach. All simulations are performed using the Real ESSI Simulator system (http://real-essi.info/).

Free Damage Propagation with Memory

Prashant Jha*, Robert Lipton**

*Department of Mathematics Louisiana State University, **Center for Computation and Technology and Mathematics Louisiana State University

ABSTRACT

We introduce a simple model for free damage propagation based on non-local potentials. The model is developed using a state based peridynamic formulation. The resulting evolution is shown to be well posed. At each instant of the evolution we identify the damage set. On this set the local strain has exceeded critical values either for tensile or hydrostatic strain and damage has occurred. For this model the damage set is nondecreasing with time and associated with damage variables defined at each point in the body. We show that energy balance holds for this evolution. For differentiable displacements away from the damage set we show that the nonlocal model converges to the linear elastic model. We provide several numerical examples modeling fatigue and fracture.

Dynamics of Thin Liquid Films on Vertical Cylindrical Fibers

Hangjie Ji*, Claudia Falcon**, Abolfazl Sadeghpour***, Zezhi Zeng****, Andrea Bertozzi*****, Sungtaek Ju******

*University of California, Los Angeles, **University of California, Los Angeles, ***University of California, Los Angeles, ****University of California, Los Angeles, *****University of California, Los Angeles, ******University of California, Los Angeles

ABSTRACT

Viscous thin liquid films flowing down vertical fibers can exhibit interesting dynamics via the formation of droplets driven by a Rayleigh mechanism with the presence of gravity. Motivated by experimental results on the effects of nozzle geometry on the dynamics of these viscous droplets by Sadeghpour et al. (2017), we further study a thin film model for the gravity-driven flow in the Rayleigh-Plateau Regime. The governing equation is a fourth-order nonlinear parabolic PDE for the film thickness that takes into consideration hydrodynamic boundary conditions, surface tension, intermolecular forces, and gravity. Time-dependent computations of the spatial evolution of the film reveal a strong influence of inlet boundary conditions that characterize different nozzle geometry. Numerical solutions of traveling wave solutions also yield information on the profile and propagation velocity of fluid beads, which are compared to experiments.

Buffering Capacity of Non-spherical Granular Materials Based on DEM Simulations with Super-quadric Elements

Shunying Ji*, Ying Yan**, Siqiang Wang***

*State Key Laboratory of Structural Analysis for Industrial Equipment, Dalian University of Technology, Dalian 116023, China, **School of civil and Safety Engineering, Dalian Jiaotong University, Dalian, 116028, China, ***State Key Laboratory of Structural Analysis for Industrial Equipment, Dalian University of Technology, Dalian 116023, China

ABSTRACT

Granular systems commonly encountered in industry or nature are comprised of non-spherical grains. Compared to spherical particles, high discretization and interlocking among particles can dissipate effectively the system energy and improve the buffer capacity. The superquadric element based on continuous function representation can construct the geometric shape of irregular particles accurately, and then its contact detection between particles can be calculated easily. In this paper we study the buffer capacity of non-spherical particles under impact load by the discrete element method (DEM). To examine the validity of the algorithms and this model, we compare with the analytical results for a single cylinder impacting a flat wall and the previous experimental result for spherical granular material under impact load, and this method is verified by the good agreement between the simulated results and the previous experiments. Furthermore, the influences of granular thickness and particle shapes on the buffer capacity are discussed. The results show that a critical thickness H_c is obtained for different particle shapes. The buffer capacity is improved for increasing the granular thickness when H<H_c, but is independent of the granular thickness and particle shapes when H?H_c. Moreover, decreasing the particle blockiness and increasing or decreasing the aspect ratio of cylinder-like particles and box-like particles have more effective buffer capacity for the non-spherical particle systems.

An Accurate Weakly Compressible SPH Method for Simulating Interfacial Multiphase Fluid Flow Involving Complex Geometries and Motions

Zhe Ji*, Michael Gestrich**, Milos Stanic***, Thomas Indinger****

*FluiDyna GmbH, **FluiDyna GmbH, ***FluiDyna GmbH, ****FluiDyna GmbH

ABSTRACT

Numerical simulations of interfacial multiphase fluid flow have a wide range of applications across engineering fields. Simulations of oil distribution in transmission systems regularly involve complex geometries and high-speed motions. Robust and accurate handling of multiple material phases and the interaction with complex moving geometries is a challenging problem for any numerical method. As a particle-based method, Smoothed Particle Hydrodynamics (SPH) conserves mass and momentum. The sharp interface condition is inherently satisfied and characterized by particles carrying distinct material properties, which is the main advantage over the grid-based methods. Nonetheless, regarding to multiphase simulations, traditional SPH suffers from several numerical difficulties and extra treatments are required in order to maintain stability and sharpness of the interface. In this work, an accurate weakly compressible SPH method is developed to simulate interfacial multiphase flow involving complex geometries and rigid-body motions. In order to decrease numerical oscillation of the pressure field, the pair-wised particle interaction is calculated by solving a one-dimensional Riemann problem. An extended HLLC Riemann solver [1] is tailored to handle interactions between different materials with general equations of state and large density ratio. For continuous region within one phase, a modified Riemann solver [2] is employed to decrease the intrinsic numerical dissipation. In addition, a generalized wall boundary condition, based on solving a one-side Riemann problem, is extended to multiphase situation to handle interactions regarding to complex moving geometries with the existence of triple points. Moreover, to go beyond 1st order of accuracy and overcome some well-known difficulties of the traditional SPH method, a second-order gradient estimator as well as the MUSCL-Hancock scheme are utilized. Lastly, to avoid the disorder of particle positions and creation of void regions, the transport velocity formulation is embedded as well. The proposed SPH method is implemented in a high performance multi-GPU code developed by FluiDyna GmbH. Extensive numerical tests including academic and industrial benchmarks are carried out in the end to validate the accuracy of proposed numerical method. The results exhibit significant improvement over traditional SPH. More physically plausible results are observed by producing better-resolved fluid structures and a more accurate pressure field. ABSTRACT

Abstract The current work presents an enhanced isogeometric analysis (IGA) [1] collocation method, where the collocation points are different from the usual Greville-abscissae. It is well known that the location of the collocation points plays an important role in the accuracy and stability of IGA collocation methods. This is particularly true for non-uniform meshes and domains generated from multi-patch geometries. We propose a collocation method based on Gaussian points [2], which has improved accuracy as compared to using C1 splines and a recovery-based error estimator can be derived by sampling the solution at particular points in the domain. Adaptivity is implemented using a hierarchical spline basis [3], which satisfies the C1 continuity requirement. The proposed approach is demonstrated for arbitrary polynomial degrees and has been tested by several benchmark problems, including multipatch domains and geometries with re-entrant corners. Key words: IGA collocation method; Gaussian-collocation points; PHT-Spline; linear elasticity; error estimation References [1] Hughes T J R, Cottrell J A, Bazilevs Y. Quasi-nonlocal Coupling of State-based Peridynamics Model with Classical Continuum Mechanics Model

Feng Jiang*, Yongxing Shen**

*University of Michigan-Shanghai Jiao Tong University Joint Institute, Shanghai Jiao Tong University, **University of Michigan-Shanghai Jiao Tong University Joint Institute, Shanghai Jiao Tong University

ABSTRACT

The peridynamics and continuum models of elasticity have their pros and cons. The peridynamics model can be naturally applied to a region where a crack propagates or damage emerges, while the continuum mechanics model is most cost efficient and easier to enforce boundary conditions. Coupling of these models provides a way to fully take advantage of their merits. However, the energy based coupling schemes usually suffer from the spurious “ghost force” effect. To relieve this issue, in this work, a quasi-nonlocal coupling technique has been developed to couple the state-based peridynamics model with continuum mechanics model. The essential idea of the coupling is that the transition region interacts with the peridynamics region in a nonlocal way while it interacts with the continuum region in a local way. In the transition region, the stiffness tensor and the influence function are modified so that both the force patch test and the energy patch test are passed at the nodal points. Since there are more equations than parameters, the parameters are determined with l^1-minimization. Numerical examples demonstrating the accuracy and efficiency of the coupling model are presented. Offline-Enhanced Reduced Basis Method through Adaptive Construction of the Surrogate Training Set

Jiahua Jiang*, Yanlai Chen**, Akil Narayan***

*University of Massachusetts Dartmouth, **University of Massachusetts Dartmouth, ***University of Utah

ABSTRACT

The Reduced Basis Method (RBM) is a popular certified model reduction approach for solving parametrized partial differential equations. It has been combined with many multiscale methods such as domain decomposition. One critical stage of the offline portion of the algorithm is a greedy algorithm, requiring maximization of an error estimate over parameter space. In practice this maximization is usually performed by replacing the parameter domain continuum with a discrete '' training " set. When the dimension of parameter space is large, it is necessary to significantly increase the size of this training set in order to effectively search parameter space. Large training sets diminish the attractiveness of RBM algorithms since this proportionally increases the cost of the offline phase. However, the large size of parameter inputs leads to high computational costs in offline stage. In this work we propose novel strategies for offline RBM algorithms that mitigate the computational difficulty of maximizing error estimates over a training set. The main idea is to identify a subset of the training set, a '' Surrogate Training Set '' (STS), on which to perform greedy algorithms. The STS's we construct are much smaller in size than the full training set, yet our examples suggest that they are accurate enough to induce the solution manifold of interest at the current offline RBM iteration. We propose two algorithms to construct the STS: Our first algorithm, the Successive Maximization Method (SMM) method, is inspired by inverse transform sampling for non-standard univariate probability distributions. The second constructs an STS by identifying pivots in the Cholesky Decomposition of an approximate error correlation matrix. We demonstrate the algorithm through numerical experiments, showing that it is capable of accelerating offline RBM procedures without degrading accuracy, assuming that the solution manifold has rapidly decaying Kolmogorov width.

A Multi-Material Structural Topology Optimization Based on Parametric Level Set Approach Using Cardinal Basis Functions

Long Jiang*, Shikui Chen**

*Department of Mechanical Engineering, State University of New York at Stony Brook, **Department of Mechanical Engineering, State University of New York at Stony Brook

ABSTRACT

As a further development of the conventional level set methods, the parametric level set method is an improvement over its predecessor in the topology optimization area. By parameterizing the level set function, the topology optimization not only can preserve clear design result boundaries but also can avoid some undesired deficiencies in the conventional level set approach, such as the reinitialization scheme. Integrated with mathematical programming, the parametric level set approach can achieve higher numerical robustness and better handling of multiple constraints. To get an accurate material property interpolation from the level set model to the physical model, the level set function is preferred to be maintained as a signed distance function (SDF). In this research, this feature is realized by introducing a distance regularization energy functional. With this energy functional minimized, the level set function around the design boundary will be maintained as a signed distance function. At the same time, the level set function can be kept flat at the locations away from the design boundaries. Overall, this type of level set function is referred as the distance-regularized level set function. By being flat at areas away from the design boundaries, the level set function can penetrate the zero level easier, improving the design robustness by creating new holes. When extended to the multi-material structure designing, different level set functions are utilized to represent different material phases, and the overlapping areas are reconciled via the Merriman-Bence-Osher (MBO) operator. However, the distance-regularized-shape level set function may cause numerical issues while applying this operator. A sub-optimization scheme is introduced to reshape the level set function before and after the MBO operation to ensure its success. Conventionally, the parametric level set approach uses radial basis function (RBF) in the parameterization. However, due to the overlapping of the neighboring RBFs, the range of the corresponding weights, to be used as the optimization design variable, cannot be explicit determined. In this research, a newly-constructed cardinal basis function (CBF) is utilized to parametrized the level set function. This CBF is equal to one at the selected node and is equal to zero elsewhere. By using this CBF in the parameterization, the design variable range can be explicitly determined, as the range of the level set function itself.

Effects of grain size and shape on the plasticity of FCC polycrystals : A Dislocation Dynamics Study

Maoyuan Jiang*, Benoit Devincre**, Ghiath Monnet***

*EDF R&D;, Department MMC, France, **Laboratoire d'Etude des Microstructures, CNRS-ONERA, France, ***EDF R&D;, Department MMC, France

ABSTRACT

From the seminal work of Hall and Petch (HP), the effect of grain size on the mechanical properties of polycrystal is well known. Nevertheless, the elementary properties responsible for the HP effect are still matter of debate. Besides, theoretical and experimental investigations are today essentially focused on polycrystals made of equiaxial grains. However, industrial materials are usually formed with grains having non-equiaxed shapes (perlite, matensite, bainite etc.). In this work, Dislocation Dynamics (DD) simulation is used to identify the elementary mechanisms controlling the HP effect at the dislocations scale. In addition, the influence of grain shape is explored by considering simple periodic polycrystalline aggregates made of grains with cube, plate or needle shapes. First, simulations have been made with a very simple periodic model of aggregates. Grain boundaries (GBs) are considered impenetrable to the dislocation gliding inside the grains. Results show that the HP effect is globally obeyed and the interaction with GBs in strongly affected by the number of active slip systems. Secondly, we designed simulations to test the influence of grain shape on the HP effect. We show that the HP effect is strongly affected by the grain shapes. A simple model based on the calculation of the dislocation mean free path is proposed to account for the influence of the grains morphology. In the context of strain gradient plasticity, the HP effect is explained by the presence of a back-stress inside the grains that emerges from strain incompatibility between grains in a deformed polycrystal. In other words, geometrically necessary dislocations (GNDs) must accumulate at GBs to accommodate the different distortion field imposed to the grains during plasticity. By virtue of the Nye's tensor, the above property can be directly tested and quantified in DD simulations. For the simplest simulation geometry, the computed back-stress as function of the distance to the GB interface can be compared with theoretical models. Essentially, a crystal plasticity field model is found to correctly calculate the back-stress amplitude close to the GB interface while the DD simulation results exhibit a decay trend for the stress components. A twist subgrain calculation accounting for the finite size of the GND microstructure gives much better agreement with the DD simulation results.

A Coupled Finite Volume Methods and Extended Finite Element Methods for the Dynamic Crack Propagation Modelling with the Pressurized Crack Surfaces

Shouyan Jiang*, Chengbin Du**

*Department of Engineering Mechanics, Hohai University, Nanjing 210098, China, **Department of Engineering Mechanics, Hohai University, Nanjing 210098, China

ABSTRACT

In this paper, we model the fluid flow within the crack as one-dimensional flow and assume that the flow is laminar, the fluid is incompressible, and accounts for the time-dependent rate of crack opening. Here, we discretise the flow equation by finite volume methods. The extended finite element methods are used for solving solid medium with crack under dynamic loads. Having constructed the approximation of dynamic extended finite element methods, the derivation of governing equation for dynamic extended finite element methods are presented. The implicit time algorithm is elaborated for the time descritizition of dominant equation. In addition, the interaction integral method is given for evaluating stress intensity factors. Then, the coupling model for modelling hydraulic fracture can be established by the extended finite element methods and the finite volume methods. We compare our present numerical results with our experimental results for verifying the proposed model. Finally, we investigate the water pressure distribution along crack surface and the effect of water pressure distribution on the fracture property.

3D Multi-scale Modeling of Microstructure Dependent Inter-granular Fracture in UO2 Using a Phase-field Approach

Wen Jiang*, Larry Aagesen**

*Idaho National Laboratory, **Idaho National Laboratory

ABSTRACT

The brittle fracture behavior of UO2 fuels is strongly influenced by the porosity and grain size distributions in the underlying microstructure. In service, there is significant evolution of these microstructural features, which can alter the fracture properties and subsequently the thermo-physical-mechanical behavior of the nuclear fuels. To incorporate these microstructural effects on the fracture behavior, a three-dimensional multi-scale modeling framework is developed in the present work. Within this framework, the grain-boundary fracture properties obtained from molecular dynamics simulations are utilized in a phase-field fracture model to investigate the inter-granular brittle crack propagation in this material. The fission gas bubble formation model is coupled with fracture to study their interaction and influence on the fracture properties. Subsequently, the parameters of an engineering scale fracture model are obtained by fitting the stress-strain evolution obtained from the phase-field simulations. This framework provides a hierarchical coupling of properties evaluated at the atomistic scale to perform more realistic engineering level predictions of fracture in nuclear fuel pellets.

Evaluation of the Benefit of Strengthening Shield Tunnels by Epoxy-bonded Filament Wound Profiles by Means of a Parametric Study Based on Multiscale Analysis

Zijie Jiang*, Xian Liu**, Lele Zhang***, Yong Yuan****, Herbert A. Mang*****

*Department of Geotechnical Engineering, Tongji University, China, **Department of Geotechnical Engineering, Tongji University, China, ***Department of Geotechnical Engineering, Tongji University, China, ****Department of Geotechnical Engineering, Tongji University, China, *****Institute for Mechanics of Materials and Structures, Vienna University of Technology, Austria

ABSTRACT

Large deformations of shield tunnels may be the consequence of a long period of operation or of nearby pit construction. Epoxy-bonded filament wound profiles (FWP) have been employed more recently to strengthen the deformed segmental tunnel linings. Full-scale tests were performed to prove the effectiveness of this method. The present paper contains a report on a macroscopic numerical model, which has been validated by comparing numerical results with experimental results. Multiscale analysis is an important ingredient of the modeling process, aimed at improving computational efficiency and fidelity. In this model, the reinforced concrete segments and the strengthening material, i.e. FWP, are simulated by means of beam elements. The joints which connect adjacent reinforced concrete segments are modeled by a group of nonlinear spring elements. Previous research has shown that the behavior of the joints may have significant influence on the mechanical behavior of the overall structure. Based on the developed numerical model, a comprehensive parametric study of the influence of several design parameters, such as, for example, Young's modulus of the FWP and the mechanical properties of the bond between the FWP and a segment of the tunnel, on the increase of both the load-carrying capacity and the overall stiffness of the structure was performed. Based on the results from this study, an optimal combination of design parameters for strengthening of shield tunnels by FWP is proposed. Moreover, the influence of the geometric dimensions of the strengthened structure and of the soil environment on the overall benefit of this strengthening was obtained. The soil environment is intergraded into the model by means of a specific scheme of loading. It is shown that this influence is smaller than the one of the geometric dimensions of the lining, which is itself relatively small.

A Link between Multiplicative Hyper-Elasto-Plasticity and Additive Hypo-Elasto-Plasticity Models: the Kinetic Logarithmic Stress Rate

Yang Jiao*, Jacob Fish**

*Columbia University, **Columbia University

ABSTRACT

Plasticity is one of the most common energy dissipation mechanisms featuring large strain in solids. Geometric nonlinearity is therefore often involved in constitutive models adopted for numerical simulation of plastic behavior of solids. Such constitutive models are usually developed through extension of the corresponding infinitesimal-deformation models into the large strain regime. Distinct large-strain plasticity models, however, can be obtained as large-strain generalizations of the same classical infinitesimal-deformation model. Understanding of the relation between these different models for the same purpose is thus of crucial importance for ensuring reliability of the computational approaches to studying plasticity. In the present study, two well-recognized categories of large-strain elasoplasticity models, i.e. the multiplicative hyper-elasto-plasticity and additive hypo-elasto-plasticity models, are analyzed with relation between them revealed. At first, the well-known additive hypo-elasto-plasticity models, which are based on additive decomposition of the rate of deformation into elastic and plastic parts, are critically examined. Through an unloading stress ratchetting obstacle test, it is shown that even a relatively recent, self-consistency-oriented variant of such models, which features the logarithmic stress rate, exhibits physical inconsistency (nonphysical energy dissipation) in an unloading process. A remedy is accordingly proposed through a simple modification to the logarithmic stress rate employed by the model. It is demonstrated that the resulting objective stress rate, termed the kinetic logarithmic rate due to its dependency on stress, renders the corresponding additive models capable of representing energy dissipation-free elastic response whenever plastic flow is absent. The multiplicative hyper-elasto-plasticity models, which are usually considered to be distinct from the additive ones in that they assume multiplicative decomposition of the deformation gradient into elastic and plastic parts, are then analyzed. It is proved that for isotropic materials the multiplicative models coincide with the additive ones if a newly discovered objective stress rate is employed by the later. This objective stress rate, termed the modified kinetic logarithmic rate, reduces to the kinetic logarithmic rate in the absence of strain-induced anisotropy. Such equivalence between the two categories of elastoplasticity models is illustrated through numerical model problems which consider homogeneous deformation along with J2 plasticity with associative plastic flow rule. It is also demonstrated in these problems that other well-known additive models, such as those based on the Jaumann and logarithmic rates, may considerably deviate from the multiplicative models.

Multi-Phase-Field Simulation of Eutectic Solidification of Binary Alloys Using a Thermodynamically Consistent Model

Peter Jimack*, Peter Bollada**, Andrew Mullis***

*University of Leeds, **University of Leeds, ***University of Leeds

ABSTRACT

This presentation will introduce the derivation of a consistent temperature equation for phase-field models of non-isothermal alloy solidification, and demonstrate its application in two dimensions for the eutectic solidification of a binary alloy based upon an appropriate multi-phase-field model. This non-isothermal model is derived using a formulation based upon the dissipative bracket of Beris and Edwards [1]. Originally designed for modelling complex fluids, the dissipative bracket has ready application in phase field modelling. In outline, we design the bracket to return the phase and alloy concentration field equations, and then use the mechanism of the bracket to automatically return the entropy field, which in turn, using generalised standard thermodynamic identities, gives the thermal field [2]. Our numerical scheme for solving the resulting system is based upon the use of spatial adaptivity and implicit time-stepping via a nonlinear multigrid scheme (the Full Approximation Scheme, FAS). The core components of this implementation will be described, including parallelization based upon a domain decomposition approach. We will illustrate both the quantitative and the qualitative importance of the non-isothermal model by contrasting numerical results against isothermal runs for a range of multiphase solidification problems, including eutectic solidification of a binary alloy, where multiple solid phases grow simultaneously in a cooperative manner.

Estimation of Bridge Frequency from Traversing Vehicle by Short-time Stochastic Subspace Identification

Nan Jin*, Themelina S. Paraskeva**, Elias G. Dimitrakopoulos***, Lambros S. Katafygiotis****

*Hong Kong University of Science and Technology, Department of Civil and Environmental Engineering, Clear Water Bay, Kowloon, Hong Kong, **Hong Kong University of Science and Technology, Department of Civil and Environmental Engineering, Clear Water Bay, Kowloon, Hong Kong, ***Hong Kong University of Science and Technology, Department of Civil and Environmental Engineering, Clear Water Bay, Kowloon, Hong Kong, ****Hong Kong University of Science and Technology, Department of Civil and Environmental Engineering, Clear Water Bay, Kowloon, Hong Kong

ABSTRACT

The eigenfrequencies of the bridge are important for various engineering applications, such as the health monitoring and the damage detection of the bridge. Over the past decade, there is a growing interest in an “indirect” approach to extract the bridge dynamic properties from vibration of the traversing vehicles. Compared with the traditional technique of installing sensors at multiple locations on the bridge, this approach is more economical, time-saving, portable and most importantly, applicable to every bridge. The traversing vehicle plays the role of a “vibration shaker” exciting the bridge, and at the same time is also a “receiver” collecting information from the bridge. Thus, it is feasible to extract modal parameters of the bridge by processing the vibration response of the vehicle. In general, the frequencies of the bridge and the traversing vehicle are not strictly constant, if the interaction between the two sub-systems and the mass of the vehicle is non-ignorable. However, their time variations are by far longer than their dynamics. For such a time-variant system, the Short-time Stochastic Subspace Identification (ST-SSI) method is proposed to extract the bridge frequencies from the vibration response and the dynamic characteristics of the traversing vehicle. Specifically, the present study assesses the accuracy and the effectiveness of the ST-SSI method that is used to identify the frequencies of a straight reinforced concrete bridge, from the vibration response of a traversing vehicle. As a proof of concept, herein the response of the vehicle is estimated from the vehicle-bridge interaction dynamic analysis. The dynamic characteristics of the vehicle are assumed known. For the needs of the ST-SSI method, the equations of motion for the vehicle and the bridge are discretized in state space, and then transformed to a series vectors by separating the known vehicle-related parameters from the unknown parameters. Finally, the observability matrix containing the bridge dynamic properties is derived by linear algebra techniques, including the Hankel matrix, LQ decomposition, orthogonal projection and singular value decomposition. The bridge frequencies identified with the proposed ST-SSI method are validated against the theoretically correct values, and conclusions regarding the feasibility of the method are drawn.

Bending Analysis of Multilayered Composite Beams in Terms of a New Mixed Global-local Higher-order Theory

Qilin Jin*, Weian Yao**, Xiaofei Hu***

*Dalian University of Technology, Dalian, China, **Dalian University of Technology, Dalian, China, ***Dalian University of Technology, Dalian, China

ABSTRACT

Accurately predicting of the transverse shear stresses for multilayered composite structure based on the equivalent single-layer theory is still challenging. In the existing method, the complex post-processing procedure based on three dimensional (3D) equilibrium equation was used. Thus, an improved equivalent single-layer theory which describe transverse shear stresses of multilayered composites accurately is expected. In this study, an accurate and computationally attractive mixed-form global-local higher-order theory (MGLHT) is developed for the bending analysis of multilayered composite beams. The theory is derived using the kinematic assumptions of global-local higher-order theory (GLHT) and employs the Reissner mixed variational theorem (RMVT). Moreover, the MGLHT retains a fixed number of displacement variables regardless of the number of layers. The benefit of the proposed MGLHT over the GLHT is that no post-processing approach is needed to accurately calculate the transverse shear stresses. The equilibrium equations and analytical solution of the present model can be obtained based on the Reissner mixed variational equation. The effects of transverse shear stress on the displacements and in-plane stress have been investigated in detail. Numerical results show that the transverse shear stresses can be accurately determined from the proposed model. In addition, the transverse shear stresses derived from the RMVT have a slight effect on displacements and in-plane stress for symmetric beams. For antisymmetric beams, such effect on transverse displacement and in-plane stress is slight, but it is significant on in-plane displacement.

A Comparative Study of Modeling Shear Band Propagation via Embedded Weak Discontinuity with Global, Local and No-tracking Strategies in Three Dimensions

Tao Jin*, Hashem Mourad**, Curt Bronkhorst***

*Los Alamos National Laboratory, **Los Alamos National Laboratory, ***Los Alamos National Laboratory

ABSTRACT

A tracking strategy has been proposed by Oliver et al. [1] to ensure the continuous propagation of discontinuity surfaces in three dimensions (3D). The basic idea of this strategy is to solve a heat-conduction type boundary value problem for a family of isosurfaces of a scalar level set function as the potential discontinuity surface in the same discretized domain of the mechanical problem. In literature, this strategy has been implemented locally (the local tracking) [2] and globally (the global tracking) [3] to model Mode I fracture via the embedded strong discontinuity. In this research, for the first time we manage to integrate the tracking strategy with the embedded weak discontinuity approach to model shear band propagation that mimics Mode II fracture in the context of explicit finite element formulation. The algorithmic and implementation details regarding the global and local tracking strategies are provided. By comparing the numerical results obtained from simulations using the global, local and no-tracking strategies with the experimental results of the split-Hopkinson pressure bar test, we demonstrate the necessity of ensuring the continuity of the shear band surface to treat shear band propagation. Moreover, we discuss the suitability and the computational cost related to the global and local tracking strategies through several numerical examples. [1]. Simulation of the Cutting Process in Softening and Hardening Soils

Zhefei Jin*, James Hambleton**

*Northwestern University, **Northwestern University

ABSTRACT

Ploughing and cutting processes in soils are difficult and inefficient to simulate using conventional approaches, such as the finite element method and discrete element method, due to the occurrence of extremely large, potentially discontinuous plastic deformation. Recently, a numerical technique for modeling this process in sands was proposed by Kashizadeh and Hambleton [1] and Hambleton et al.[2]. This approach is based on incremental plastic analysis, which has high efficiency and stability to capture the essential physics and features of the problem. The present study refines this technique in two key respects. Firstly, a shear band with finite thickness is incorporated in the new model, thus introducing a key length scale and parameter that influences the predicted deformed shape. Secondly, and more importantly, a more sophisticated material law is implemented. The effects of hardening and softening, as well as the dilatancy and compaction within the shear band, are introduced. With the modified model, it is observed in the case of hardening (compaction) that the occurrence of multiple successive shear bands appearing at variable locations gives the impression of continuous shearing. This is markedly different from the previously predicted response in the case of softening (dilatancy). In that case, the shear bands appear at distinct locations, and the transition from one location to the next is reflected in distinct peaks in the force-displacement history [1,2]. In the more general case, where an initial hardening phase is followed by softening, only one peak force is obtained in the modified model. The computational results are compared with some preliminary experimental data obtained in the Soil-Structure and Soil-Machine Interaction Laboratory at Northwestern University, which utilizes a six-axis robot for actuation and data acquisition. Eigenspace-Based Characterization of Structural Uncertainty in Large-Eddy Simulation Closures

Lluis Jofre*, Stefan Domino**, Gianluca Iaccarino***

*Stanford University, **Sandia National Laboratories, ***Stanford University

ABSTRACT

Large-eddy simulation (LES) has gained significant importance as a high-fidelity technique for the numerical resolution of complex turbulent flow. In comparison to direct numerical simulation (DNS), LES approaches reduce the computational cost of solving turbulent flow by removing small-scale information from the conservation equations via low-pass filtering. However, the effects of the small scales on the resolved flow field are not negligible, and therefore their contribution in the form of subgrid-scale (SGS) stresses needs to be modeled. As a consequence, the assumptions introduced in the closure formulations result in potential sources of structural uncertainty that can affect the quantities of interest (QoI). Therefore, the aim of this work is to characterize their model-form uncertainty and its impact on the QoIs by means of recently developed eigenspace-based strategies [1,2,3] that decompose the SGS stress tensor in terms of magnitude (trace), shape (eigenvalues) and orientation (eigenvectors) to facilitate the analysis. In the presentation, the strategy will be described in detail and investigations based on filtered DNS and LES of turbulent free shear flow will be discussed. [1] L. Jofre, S. P. Domino, and G. Multimesh: Finite Element Methods on Arbitrarily Many Intersecting Meshes

August Johansson*, Mats Larson**, Anders Logg***, Benjamin Kehlet****

*Simula Research Laboratory, **Umea University, ***Chalmers University of Technology, ****Simula Research Laboratory

ABSTRACT

We will present a framework for expressing finite element methods on arbitrarily many intersecting meshes: multimesh finite element methods [1]. The framework enables the use of separate meshes to discretize parts of a computational domain, such as the components of an engine, the domains of a multiphysics problem, or solid bodies interacting under the influence of forces from surrounding fluids or other physical fields. Multimesh finite element methods are particularly well suited to problems in which the computational domain undergoes large deformations as a result of the relative motion of the separate components of a multi-body system. This is a challenging situation if one would use a single mesh. The key feature of the framework is that arbitrarily many (but finite) meshes are allowed to intersect. To make this possible, accurate quadrature rules for performing the necessary volume and boundary integrals are crucial. We will in this talk present a novel procedure to systematically construct quadrature rules with appropriate positive and negative weights using a basic result from combinatorics. Furthermore, suitable stabilization are needed to ensure an optimal method also for elements of high order. Here we follow [2]. The condition at the interface (continuity) is enforced weakly by the Nitsche method. In the presentation, we formulate the multimesh finite element method for the Poisson equation and show that it is optimal and stable. We also present numerical examples to demonstrate the optimal order convergence also for high order elements, optimal conditioning of the linear system, the numerical robustness of the formulation and implementation, as well as the applicability of the methodology. On the Modelling of Technical Rubber Regarding Multiphysical Environmental Conditions

Michael Johlitz*, Alexander Lion**

*Institute of Mechanics, Bundeswehr University Munich, Germany, **Institute of Mechanics, Bundeswehr University Munich, Germany

ABSTRACT

In more or less all thinkable applications, polymer parts are thermomechanically loaded and exposed to different environmental media. In the most general case, the loadings are time-dependent and nonstationary and the composition of the media can change. An example is a hydraulic tube of a dredge which consists of fibre reinforced elastomers. The outer side of the tube is surrounded by water, dry or by humid air with a time-dependent temperature and its inner side is in contact with hydraulic oil whose temperature and pressure are time-dependent too. The outer side is also commonly also exposed to electromagnetic radiation like UV. The combination of all these influences leads to diffusion, dissolution, physicochemical reactions and changing material properties of the polymer. In order to simulate such phenomena with numerical methods, it is necessary to combine the theory of continuum mechanics with thermodynamics, chemistry and material transport. Due to the complex nature of these problems, it is impracticable to formulate one single model that can take all possible phenomena into account. As a good starting point, the thermomechanical balance equations are formulated for an open system which consists of only two materials: a deformable solid and a liquid. The liquid can diffuse into and out of the solid and can react with it. The diffusion is accompanied by reversible or irreversible swelling and changing material properties of the solid. Based on the structure of the balance relations and motivated by experience, a constitutive model for a suitable thermodynamic potential is developed and evaluated. For simplification, the dry solid is assumed to be nonlinearly elastic and the liquid to be non-viscous. The talk closes with the discussion of the final set of equations and some numerical simulations.

Predicting Baseplate Preheating Effects on Residual Stress and Microstructure in LENS Parts

Kyle Johnson*, Theron Rodgers**, Shaun Whetten***, Joseph Bishop****, Phillip Reu*****, Kurtis Ford******, Michael Stender*******, Lauren Beghini********

*Sandia National Laboratories, **Sandia National Laboratories, ***Sandia National Laboratories, ****Sandia National Laboratories, *****Sandia National Laboratories, ******Sandia National Laboratories, *******Sandia National Laboratories, ********Sandia National Laboratories

ABSTRACT

Additive Manufacturing (AM) has many potential benefits as a manufacturing technique such as complex shape production, rapid prototyping capability, and cost reduction. However, barriers to widespread adoption still exist in the form of detrimental effects like high residual stresses and non-uniform grain microstructures. Both of these effects are highly dependent on the extreme thermal gradients and high cooling rates found in the AM process. Prediction of the resulting residual stress profile and microstructure opens up many options for process optimization in order to tailor microstructure and stress profiles. This work presents methods of predicting the thermal, residual stress, and resultant microstructure for 304L stainless steel cylinders using the Laser Engineered Net Shape (LENS) AM process. The spatial and temporal evolutions of thermal history are first modeled using the Sierra finite element code. The thermal history is then used as input into a solid mechanics simulation in which material is deposited and builds residual stress upon cooling due to thermal strain. The material constitutive behavior is modeled using the Bammann-Chiesa-Johnson temperature and history-dependent viscoplastic internal state variable model. In addition to room temperature, four additional baseplate preheat temperatures up to 450?C were then modeled to investigate the effect on residual stress. Corresponding builds were produced and relaxation-based residual-stress measurement techniques were used to compare results to those predicted by the simulations. Finally, the thermal model is used in a Potts Kinetic Monte Carlo simulation using the SPPARKS code suite. Grain formation and solid-state evolution is predicting by using a cubic lattice of sites with grain “spins” that switch to neighboring spins based on a temperature-dependent grain mobility. Rapid grain growth occurs in the high thermal gradients near the melt pool and decreases with distance. The microstructure predictions for each preheat temperature are presented, along with experimental results. Peridynamics Modelling of Weibull-Type Behaviour in Ceramic Nuclear Fuel Pellets

Lloyd Jones*, Glyn Rossiter**, Mark Wenman***

*Imperial College London, **National Nuclear Laboratory (UK), ***Imperial College London

ABSTRACT

During operation, nuclear fuel experiences large temperature changes, with a steep thermal gradient from the hot centre to the cooler surface. Some information may be gleaned from in situ measurements at test reactors, and some from studying fuel once it is removed from service. Both of these options are expensive and limited. Computer models potentially allow for much greater insight into the processes that damage fuel, and those that allow it to function properly. Since uranium dioxide (UO2) fuel is ceramic, its fracture behaviour should be well described by Weibull theory, also known as weakest link theory. Weibull theory posits that ceramic fracture is caused by cracks nucleating on microscopic flaws. Since these flaws are of a distribution of sizes, the fracture strength of ceramics follow a similar distribution. Peridynamics is well suited to modelling this problem due to its strengths in handling discontinuities. Randomisation of bond strengths is common in peridynamics(1). In this work, a link is made between the random properties of ceramics and the random strengths of the peridynamics bonds. The problems with simple randomisation methods are discussed, and a method for recreating Weibull characteristics in peridynamics simulations is presented. REFERENCES 1. Oterkus S, Madenci E. *Sandia, **Sandia, ***Sandia, ****Sandia, *****Sandia, ******Sandia, *******Sandia

ABSTRACT

Material variability originating from heterogeneous microstructural features, such as grain and pore morphologies, can have significant effects on component behavior and creates uncertainty around per- formance. Current engineering material models typically do not incorporate microstructural variability explicitly, rather functional forms are chosen based on intuition and parameters are selected to reflect mean behavior. Conversely, mesoscale models that capture the microstructural physics, and inherent variability, are impractical to utilize at the engineering scale. An enhanced design methodology must be developed for materials with significant variability, such as current additively manufactured metals. To address these challenges we have developed a method based on the Embedded Uncertainty for- mulation of Sargsyan, Najm, and Ghanem (2015) to calibrate distributions of material parameters from high-throughput experimental data. With this method, material variability is directly associated with commonly-used material parameters using a chosen nominal model. One of the benefits of this approach is that expert knowledge can be extended to interpret the effect of (hidden) microstructure on variable mechanical response. In a complementary effort, we are also developing machine learning techniques to handle the large volume of data from high-throughput methods. The focus of this aspect of the work is on adapting common machine learning models, such as neural networks, to obey the same exact properties and symmetries as traditional constitutive models while representing features in the data in a flexible, bias-less manner. A Particle Based Modelling Approach for Predicting Charge Dynamics in Tumbling Ball Mills

Pär Jonsén*, Simon Larsson**, Bertil Pålsson***, Samuel Hammarberg****, Göran Lindkvist*****

*Division of Mechanics of Solid Materials, Luleå University of Technology, Sweden, **Division of Mechanics of Solid Materials, Luleå University of Technology, Sweden, ***Minerals and Metallurgical Engineering, Luleå University of Technology, Sweden, ****Division of Mechanics of Solid Materials, Luleå University of Technology, Sweden, *****Division of Mechanics of Solid Materials, Luleå University of Technology, Sweden

ABSTRACT

Wet grinding of minerals in tumbling mills is a highly important process in the mining industry. During grinding in tumbling mills, lifters submerge into the charge and create motions in the ball charge, the lifters is exposed for impacts and shear loads that will wear down the lifters. Increased loading can accelerate the wear and the lining has to be replaced. Replacing the lining is an expensive and time consuming operation that is preferred to be done within planned maintenance stops. Prediction of the charge motion and wear rate for different grinding operations and linings are therefore desirable to predict the lining life. Modelling of wet grinding in tumbling mills that include pulp fluid and its interaction with both the grinding balls and the mill structure is an interesting challenge and some different approaches have been suggested, see [1-2]. For an effective and successful prediction, the numerical model has to be able to handle the pulp fluid and its simultaneous interactions with both the ball charge and the mill structure, in a computationally efficient approach. In this work, the pulp fluids are modelled with a Lagrange based method called incompressible computational fluid dynamics, (ICFD), which gives the opportunity to model free surface flow. This method gives robustness and stability to the fluid model and is efficient as it gives possibility to use larger time steps than the conventional CFD. The ICFD solver can be coupled to other solvers as in this case the finite element method, (FEM) solver for the mill structure and the discrete element method (DEM) solver for the ball charge. The combined ICFD-DEM-FEM model can predict both charge motion and responses from the mill structure, as well as the pulp liquid flow and pressure. The numerical grinding case presented here is validated against experimentally measured driving torque signatures from an instrumented small-scale batch ball mill, see [3]. This approach opens up the possible to predict the volume of the high-energy zone and optimise lifter design and operating conditions. The ICFD solver show improve efficiency and robustness for studying tumbling mill systems and can predict the charge dynamics in such systems. [1] Jonsén, P. et al., Minerals Enginering. Mixed Nonlinear Localization: Two-Scale Approximation of the Robin Parameter

Hinojosa Jorge*, Saavedra Karin**

*Universidad de Talca, Chile., **Universidad de Talca, Chile.

ABSTRACT

Performing nonlinear analysis of large structures at fine scale is one of the industrial challenges of our times. The post-buckling analysis of aeronautical structures is a typical example. During the structural tests for certification achieved on complete fuselages of aircraft, local buckling of the skin between stiffeners occurs. For increasing loads, these nonlinear areas can expand and provoke redistributions of stresses in the structures. For workloads usually met in service, these phenomena are reversible, the material remaining in the elastic domain. However, they can provoke stress concentrations at the bases of stiffeners and may be at the origin of local damages leading to global failure. The idea of the nonlinear localization strategy [1, 2, 3] is the treatment of the localized nonlinearities at the subdomain level, avoiding dealing with a high number of different local bucking modes, improving the robustness of the method. The other point on this strategy is to used a mixed domain decomposition scheme in order to favours neither the displacement continuity, which is a too stiff condition, nor the interface equilibrium, but a combination of both (a Robin-like condition). This mixed scheme shares similar features with continuation methods to control the algorithm convergence. In previous works [1] was shown that the decomposition choice could lead to different equilibrium paths depending on the followed “numerical” path. When a subdomain that buckles is decomposed into two subdomains its behaviour could be modified leading to a different solution. In [1] it also has been shown the convergence equilibrium of a stiffened panel when skin buckling occurs, showing a 5-lobes buckling for the non-subdivided subdomain and 4-lobes for the subdivided subdomain. Also, the equilibrium path are consequently different and the global buckling deformed shape are different as well as the global compressive behaviour, reducing the final load in 30%. In this work, we focus on the choice of dedicated Robin operator for common industrial features. A two-scale approximation [2] is implemented. Coarse-grained Twinning Characteristics for Crystal Plasticity Gleaned from Atomistic Simulations

Shailendra Joshi*

*University of Houston

ABSTRACT

We employ molecular dynamics (MD) simulations to investigate the evolution of extension twinning in magnesium single crystals under a range of multi-axial loading. The objective is to understand the evolution of variant twin volume fraction and number of twins, which enable describing the evolution of the twinning at the coarser, crystal plasticity length-scales. We investigate the role of stress state in the activation and interaction between different twin variants through signatures of nucleation, growth, coalescence and detwinning. Significant dislocation plasticity occurs on basal and prismatic <a> slip systems during and after twinning. Prior to coalescence phase, twinning volume fraction exhibits an exponentially decaying distribution. We propose phenomenological formulae for the evolution of volume fraction and number of twins, which should serve as a starting point for constructing improved coarse-grained crystal plasticity models for twinning.

Gradient Crystal Plasticity Modeling of Twin Boundary Migration Effects on Deformation Stability in Nanotwinned Metals

Shailendra Joshi*

*University of Houston

ABSTRACT

Our ongoing work is to understand the role of twin boundaries (TBs) in the deformation and failure characteristics of nanotwinned (NT) materials. To that end, we implemented a gradient crystal plasticity model within a finite element framework, which accounts for slip and slip rate gradients that are intrinsically coupled to TB migration. Using this framework, we extract intricate coupling between TB migration and twin size, load orientation and the energy barrier of dislocation-TB interactions. The resulting kinetic relation is then adopted in probing the size-dependent stress-strain responses and microstructural instabilities in polycrystalline NT materials without explicitly modeling twins.

A 3D Partitioned Coupled Variational Formulation for Multifield and Multiphase Modeling

Vaibhav Joshi*, Rajeev K. Jaiman**, Pardha S. Gurugubelli***

*National University of Singapore, **National University of Singapore, ***National University of Singapore

ABSTRACT

A 3D coupled variational framework has been proposed to solve a nonlinear dynamical multifield problem of multiphase turbulent fluid flow interacting with a flexible multibody dynamic system. The proposed coupled solver is motivated by the modeling of offshore vessel-riser system which is exposed to harsh environmental conditions, viz, free-surface ocean waves and high velocity ocean currents. The dynamical response of such offshore system can be quite challenging due to strong two-way interaction of the vortex-induced vibration of riser and the wave-induced motion of vessel. We address three key numerical challenges in the proposed variational coupled formulation: (i) stable and robust coupling of incompressible turbulent flow with a system of nonlinear elastic bodies described in a co-rotated frame, (ii) a conservative and positivity preserving two-phase coupling based on the phase-field approach, and (iii) the stable integration of phase-field solver with fluid-flexible multibody solver involving moving boundaries. In the proposed formulation, the modeling of the air-water interface is accomplished by the positivity preserving variational method [1] applied to the conservative Allen-Cahn phase-field equation [2] and the turbulence is modeled by Delayed Detached Eddy Simulation [3]. The structural domain consisting of multibodies is solved using a nonlinear co-rotational method, whereas the fluid domain is solved by the Petrov-Galerkin variational method. The flow, turbulence and two-phase equations are written in an arbitrary Lagrangian-Eulerian (ALE) framework which takes into effect the moving boundaries of the structure. This multifield formulation consisting of fluid, structure, turbulence, two-phase and ALE, is solved in a partitioned iterative implicit manner. The partitioned scheme utilizes the nonlinear iterative force correction at the fluid-structure interface for stability at low structure-to-fluid mass ratios typically found in the offshore systems. We verify accuracy and robustness of our formulation on simple and reproducible academic examples and applicability to large-scale scenario of offshore vessel-riser system interacting with ocean waves and current flow. Goal-oriented Adaptivity for Micromorphic Problems Based on Duality Techniques

Xiaozhe Ju*, Rolf Mahnken**

*University of Paderborn, **University of Paderborn

ABSTRACT

It is well-known that the classical Cauchy-Boltzmann continuum, in spite of its simplicity, has its limitations, e.g. on the simulation of strain localization phenomena or size effects. For a remedy, one may resort to the so-called generalized continuum theories, see e.g. [1] and references therein. Amongst others, we consider a class of higher order continua, namely the micromorphic continua, where the kinematics is enriched by means of a microstructure undergoing an affine micro deformation. The increasing number of the degrees of freedom in such a theory clearly motivates an application of adaptive methods. In this contribution, we present a general framework of goal-oriented adaptivity for such kind of problems. To this end, we derive a goal-oriented error estimator, leading to an effective adaptive method for controlling the discretization errors of the finite element method. For illustration, we address both elasticity and plasticity problems. For linear elastic micromorphic problems, we show the consistency of the resulted dual problem, ensuring an optimal convergence order, see [2]. For plasticity (time-dependent) problems, as shown in [3], we construct a specific dual problem tracking backwards in time to account for the accumulation of errors over time. Additionally, numerical examples are shown. References: [1] T. Dillard, S. Forest, P. Towards Efficient Isogeometric Matrix Assembly: Partial Tensor Decomposition and Numerical Quadrature Rules for Trimmed Domains

Bert Juettler*, Angelos Mantzaflaris**, Felix Scholz***

*Johannes Kepler University, Linz, **Johannes Kepler University, Linz, ***RICAM, Austrian Academy of Sciences

ABSTRACT

The efficient assembly of matrix elements for isogeometric simulations poses many challenging problems. On the one hand, the high polynomial degrees and the large overlap of the basis functions motivates the use of new approaches to achieve computational efficiency. Among the various approaches to address this issue, we mention the use of special numerical integration techniques for spline functions [1]. On the other hand, the use of trimming operations increases the geometric complexity of the domains. Consequently, there is a need to develop suitable techniques for numerical integration. More information is provided in the survey article [2]. The talk reports on two recent developments to address these two issues. First, we describe the method of partial tensor decomposition, which allows to increase the efficiency of numerical quadrature by systematically exploiting the tensor-product structure of isogeometric discretizations, thereby reducing the dimension of the occurring integrals. Compared to the full decomposition approach, which has been established in [3], it is easier to implement, since it relies entirely on standard techniques from numerical linear algebra. It also provides a further reduction of the computational costs when used in connection with h-refinement. Second, we show how to derive special quadrature rules for trimmed domains by considering the implicit representation of the trimming curves and surfaces. This representation can be obtained via (exact or approximate) implicitization. Based on the implicit form, we use linearization to simplify the trimmed elements. Our quadrature rules combine integration over the simplified trimmed element with an integration of an auxiliary function over the linearized cutting curve or surface. The latter integration gives a correction term that restores the required order of convergence. This approach allows us to perform numerical quadrature on trimmed domains without having to compute intersections explicitly. Both methods have been implemented in the G+Smo C++ library [4]. Architected Piezoelectrics for Dynamic Control of Mechanical Wave Propagation

Abigail Juhl*, Carson Willey**, Vincent Chen***, Phillip Buskohl****

*Air Force Research Laboratory, **Air Force Research Laboratory, ***Air Force Research Laboratory, ****Air Force Research Laboratory

ABSTRACT

Periodically repeating resonant substructures are the building blocks of many acoustic metamaterials and phononic crystals. The usefulness of a component made from such an array of unit cells is that the vibratory, or wave propagation behavior can be engineered to create frequency bands in which mechanical motion is forbidden, or highly attenuated, termed bandgaps. One major drawback of producing bandgaps through structural design is that the bandgap is fixed once the structure is decided upon leaving no opportunity for bandgap reconfiguration. In order to create a tunable bandgap structure some portion of the locally resonant unit cells must be variable and controllable by outside, preferably remote, stimulus. An approach for tuning a structure experiencing forces or practical origin and magnitude is the use of piezoelectric elements acting as electrically tunable stiffness and damper elements. Due to the difficulty in fabricating complex architectures in piezoelectric materials and integrating electrodes, research in this area has been mostly theoretical, or limited to 1D plates or patches of piezoelectrics. This talk will focus on steps made towards simulating structures augmented by the addition of shunted piezoelectric patches for the suppression of particular structural mode shapes.

Fast Spectral Solvers without Linear Reference Medium

Till Junge*

*École polytechnique fédérale de Lausanne

ABSTRACT

In the field of computational homogenization of periodic representative volume elements (RVE), over the last two decades, fast Fourier transform (FFT)-based spectral solvers have emerged as a promising alternative to the finite element method (FE). Most of these spectral methods are based on the work of Moulinec and Suquet [1] and split an RVE's mechanical response into the response of a linear reference medium and a periodic fluctuation due to heterogeneities. The main advantage of this formulation over FE is that it can be both significantly faster and have a much smaller memory-footprint. The two main problems are 1) the choice of the linear reference medium, which is typically based on heuristics, is not trivial and has a strong impact on the method's convergence (A bad choice can render the method non-convergent), and 2) a high-frequency numerical artifact (Gibbs ringing) around areas of sharp phase contrast due to non-uniformly converging Fourier series coefficients. Numerous studies have suggested mitigations to both of these problems (e.g. [2]), but they have remained substantial disadvantages compared to the more expensive, but also more robust FE. Recent work by Zeman et al. [3] proposes a new formulation for spectral solvers which dispenses with the linear reference problem and converges unconditionally. We present µSpectre, an open implementation of this novel method and use it to show that the new approach is frequently more computationally efficient than its linear reference medium-based predecessors, converges in the presence of arbitrary phase contrast - including porosity - and eliminates or drastically reduces Gibbs ringing. IGA-BEM for Lifting Flows

PANAGIOTIS KAKLIS*, SOTIRIOS CHOULIARAS**, CONSTANTINOS POLITIS***, ALEXANDROS-ALVERTOS GINNIS****, KONSTANTINOS KOSTAS*****

*UNIVERSITY OF STRATHCLYDE, GLASGOW (UK), **UNIVERSITY OF STRATHCLYDE, GLASGOW (UK), ***TECHNOLOGICAL EDUCATIONAL INSTITUTE OF ATHENS (GR), ****NATIONAL TECHNICAL UNIVERSITY OF ATHENS (GR), *****NAZARBAYEV UNIVERSITY, ASTANA (KZ)

ABSTRACT

Combining Iso-Geometric analysis (IGA) with Boundary Element Methods (BEM) for inviscid lifting flows imposes a number of difficulties. Firstly, an IGABEM collocation scheme has to take into account the tangent-plane discontinuity occurring along the trailing edge (TE). More important, the scheme has to handle the non-linear Kutta condition, securing continuity of the normal velocity and pressure through the a-priori unknown wake, a force-free boundary surface emanating from TE. In this presentation we shall review the status of our work towards developing a pair of IGABEM collocation schemes for computing steady lifting flows around 2D and 3D bodies , e.g., hydrofoils, marine propellers; [1,2]. In the latter case, the ansatz functions are inherited from T-spline representations which are free from singularities occurring, e.g., at the tip of a propeller blade, when NURBS are used. Topology Optimization for Shape-Memory Alloys

ZILIANG KANG*, Kai James**

*University of Illinois at Urbana-Champaign, Department of Aerospace Engineering, **University of Illinois at Urbana-Champaign, Department of Aerospace Engineering

ABSTRACT

Shape-memory alloys are a unique class of active materials, as some of them exhibit a bidirectional shape-memory effect. This effect enables shape memory alloys to deform and recover under a prescribed temperature cycle, which makes shape memory alloys an ideal material for use in self-actuated morphing applications. However, the most widely used titanium-based shape memory alloys have large electrical resistance when using joule heating from electrical current as a source of actuation. By contrast copper-based shape-memory alloys are efficient electrical conductors but they have poor deformation caused by the shape memory effect. Therefore, we present a novel method for the design of shape-memory activated structures based on a multimaterial topology optimization method, which aims to create structures that are manufacturable via 3D printing, and also exhibit desirable shape-memory effects. Assuming isotropy throughout the structure, we consider a two-dimensional stress-free problem in which we optimize the distribution of several distinct candidate materials plus a void phase to get optimal strain caused by the shape-memory effect, under a predetermined temperature cycle caused by joule heating. The thermomechanical response of the structures is modeled using nonlinear, multi-physics finite element analysis. The electrical conductivity and shape-memory transformation temperature of each finite element within the discretized structure are represented via a series of coefficient functions that implicitly define the material distribution. The design task is carried out using gradient-based optimization, with the design sensitivities obtained via adjoint sensitivity analysis. We demonstrate the proposed design framework using a series of two-dimensional thermomechanical benchmark problems. Keywords: shape-memory alloys, topology optimization, multimaterial optimization, multi-physics design

The Contact Problem of a Two Deformable Orthotropic Elastic Solids

Aysegul KUCUKSUCU*

*Unfortunately, Bursa Orhangazi University, which was the university I worked, closed after 15th July 2016 coup attempt in Turkey. So, I could not write the name of the university.

ABSTRACT

In this study, the contact problem of two deformable orthotropic solids is considered. The problem is solved by using analytical method. The Poisson's ratio of the cylinders are assumed to be constant and the contact is frictional, obeying the Coulomb law of dry friction with constant friction coefficient and the contact is assumed to be the Hertzian. In the formulation of the contact problem, it is assumed that the principal axes of orthotropy are parallel and perpendicular to the contact. Four independent engineering constants are replaced by a stiffness parameter, a stiffness ratio, a shear parameter, and an effective Poisson's ratio, Cauchy-type singular integral equations of the mixed-boundary value contact problem are prevailed using Fourier transform and solved numerically to obtain contact pressure and in-plane stress distribution. The analytical solution of the study presents correlation between contact stress and in-plane stress distributions and orthotropic material parameters, length parameters and the coefficient of friction.

Modelling and Simulation of Engineered Cementitious Composites with Shape Memory Alloy Fibres

Mieczyslaw KUCZMA*

*Poznan University of Technology, Institute of Structural Engineering

ABSTRACT

A thermodynamically consistent model for cementitious composites reinforced with shape memory fibres is considered. Cementitious composites, including concrete being the most used structural material, possess some inherent shortcomings. They are very weak in tension in comparison to their compressive strengths and are brittle materials with low ductility which results from development of micro-cracks. The addition of shape memory alloy fibres to cementitious composites will enhance their ductility and damping capacity. Shape memory alloys exhibit very large (up to 8-10%) recoverable strains, as a result of stress and temperature induced transformations between austenite and martensite phases. The SMA are smart materials which demonstrate unusual phenomena: the shape memory effect, and pseudoelasticity (superelasticity) with characteristic flag-shaped hysteresis loops in loading/unloading cycles. For cementitious matrix of the composite a constitutive model for concrete with progressive damage is used, whereas for the monolithic shape memory alloy fibre a constitutive model is applied that accounts for occurrence of three phases (austenite and two variants of martensite). The evolution law for volume fractions of martensite variants is derived from the second law of thermodynamics in Clausius-Duhem inequality form. From the computational point of view, the deformation process of the cementitious composite with shape memory fibres is discretized in space by the FEM and solved incrementally in time as an implicit strain driven problem (sequence of complementarity problems). Results of numerical simulations will illustrate the observed influence of shape memory alloy fiber reinforcement on the response of the cementitious composite.

Modelling and Simulation of Dynamic Fracture of Polycrystalline TiAl Alloys under High Velocity Particle Impact

Mohammad Rizviul Kabir*

*German Aerospace Center

ABSTRACT

Multi-phase polycrystalline TiAl alloys show complex fracture behaviour under high velocity particle impact (HVPI). The front-side damage and back-side crack networks are found to be microstructure sensitive, which implies that the local microstructure variations of this alloy may lead to unwanted blade failure during operation. Therefore, it is important to know how these microstructures influence crack initiation and crack propagation. To this aim in the present work a numerical modelling approach has been proposed that takes into account the microstructural statistics via polycrystal modelling and a combined damage and fracture ansatz for impact fracture behaviour. The polycrystal models were generated using Voronoi cells considering grain aspect ratio and texture. The grain boundaries were modelled applying thin cohesive layers between grains. Two types of microstructures have been studied; one with the globular grains and the other with elongated grains. The material data were obtained from detail experimental work [1]. The proposed approach allows a quantitative prediction of crack networks as observed by the experiments for different TiAl microstructures. Under dynamic impact, cracks mainly propagate through grain boundaries which have been captured using cohesive damage model. It was found that for globular grains star-shaped crack network was formed and for the elongated grains the crack extends longitudinally. The length of the crack branches can be studied for varying damage parameters at the grain boundaries. This information is useful for further analysis of fatigue life and durability of the TiAl alloy. [1] S. Gebhard, Partikel-Impact an ?-Titanaluminid-Legierungen. Phase Field Modeling of Fission Gas Bubble Growth in Nuclear Fuels

Amy Kaczmarowski*, Dane Morgan**, Shiva Rudraraju***

*Sandia National Laboratories, **University of Wisconsin Madison, ***University of Wisconsin Madison

ABSTRACT

Fission gas bubble growth is critical to the behavior of nuclear fuels in fission nuclear reactors. Bubbles can induce fuel swelling that could lead to fuel-cladding contact, generate increased stresses on the cladding and lead to undesired fuel-cladding chemical interactions. In addition, the bubbles also decrease the thermal conductivity of the fuel and thus effect the performance of the nuclear reactors. In this talk, we present a novel coupled phase field formulation for tracking bubble growth and the resulting deformation of the surrounding matrix material. The model demonstrates the application of moving Neumann conditions corresponding to the gas pressure from the equation of state, and its relative advantage over other relevant interface tracking methods. Numerical examples will demonstrate the evolution of mechanics and stress concentrations in single bubble and multiple bubble growth scenarios.

Key words: Dynamic interaction, Coupling vehicle-track modeling, short wavelength defect, long wavelength defect, coupled rail surface defects.

Abstract. Every day, over 100 million of train traffics are being operated globally. The first priority in train operation management is '*safety*'. During each operation, the dynamic interactions between vehicle and track usually impose vibrations and acoustic radiations and become a moving source of vibroacoustics along the railway network. Especially when there is imperfection of either wheel or rail, the dynamic amplification of loading conditions and reflected vibration effects on infrastructure and rolling stocks is significantly higher. In practice, imperfection of rail tracks is inevitable and can be classified into short wave length and long wave length defects. The imperfections can statistically induce high-intensity impact loadings up to 25% of *annual* track loading conditions. The short wavelength defects include high-frequency related rail surface defects such as dipped joint rails, rail squats, rolling contact fatigues (RCFs), rail gabs and crossing noses. The long wavelength defects are those associated with low frequency vibrations such as differential track settlement, mud pumping, bridge ends, stiffness transition zone, etc. Most previous studies into vehicle-track interactions were concerned only to a single one of the defect separately. This study is the world first to evaluate the coupling dynamic vehicle-track interactions over coupled short and long wavelength rail defects. The vehicle model has adopted multi degrees of freedom coupling with a discrete supported track model using Herzian contact theory. This paper highlights the nonlinear dynamic impact load factors experienced by railway track components due to wheel/rail contacts. The insight into the nonlinear phenomena will enable predictive track maintenance and risk-based track inspection planning adaptation to enhance public safety and reduce unplanned maintenance costs.

1 INTRODUCTION

There are two types of modern railway tracks suitable for various purposes of railway operations. A selection of trackform (ballasted vs ballastedless track) is commonly based on capital cost, lifecycle cost, asset management and operations (e.g. train speeds, axle load, and ride quality). For over 200 years, railway tracks have evolved. Considering the whole life cycle values, modern ballasted railway tracks have become the most efficient and effective infrastructure for the railway industry operating *below* 250 km/h of train speed for over centuries. The ballasted tracks have been tailored and optimised over and over; and they are often used in light rail tracks, metro networks, suburban rail network and intercity rail lines since they are relatively inexpensive and quite superior in terms of maintainability and constructability [1-4]. In contrast, ballastless tracks or concrete slab tracks are often utilised for highspeed rail lines (with train speed over 250 km/h) to reduce maintenance costs due to highspeed related swift degradation of traditional track components (e.g. accelerated densification and dilation of ballast, poor ride comfort due to differential track settlement/stiffness, ground-borne noise and vibration problems, etc.) [1, 5-9]. In practice, railway maintainers and operators are suffering from many of rail surface defects that lead to increased maintenance (either planed or unplanned), operational downtime and delay, more frequent monitoring and track patrol, and possibly the broken rails leading to train derailments [10-12].

Commonly, urban rail operators experience social problems of ground-borne, structure-borne noise and vibration induced by short and long wavelength rail defects. For instance, extra level of noise excited by rail squats (short wavelength type) was observed by residents near Woolloomooloo viaduct in Sydney, Australia [13-14]. Reportedly, the cost of rail replacement due to rail squats and studs has become a major part of the whole track maintenance cost in European countries [15]. Note that the rail squats and studs are typically classified as the growth of any cracks that has grown longitudinally through the subsurface. The subsurface lamination crack later results in a depression of rail surface sometimes called ‘dark spot’ [16]. There are two initiation types of the rail surface defects. Such rail defects are commonly referred to as ‘squats’ when they were initiated from rolling contact fatigue (RCF) cracks, and as ‘studs’ when they were associated with white etching layer due to wheel slips or excessive tractive effort [16].

Moreover, with heavier and faster trains, the dynamic load transferring on to track and its components such rails, sleepers, ballast and formations is higher and amplified by the traffic speeds and rail surface defects. These dynamic impact loading conditions often damage the track support and cause initial differential settlement and plastic deformation. The track issue does not stop here. Such the plastic deformation and initial differential settlement further form and couple with short wavelength defects (if any) to exponentially aggravate the dynamic loading condition [17-19]. Therefore, it is highly important to understand the coupled dynamic effect of rail defects on the rail infrastructure so that rail operators and maintainers can develop suitable cost-effective strategies for operations and maintenance. An example of strategies is to carry out preventative track maintenance (such as re-tamping, re-grinding and ballast cleaning when early sign of damage is inspected). In many regional railways (such as freight services), speed restrictions have been adopted to delay the maintenance regime when the rail defects exist. Note that these strategies are often called ‘Base Operating Conditions (BOCs)’ in railway industry practices. The BOCs have been developed from internal R&D activities and extensive empirical experience in

the rail industry over the centuries. On this ground, the established railway authorities of course do not lack of expertise and best practices. However, they might lose sight of nonlinear combined effects and might lead to inefficient and ineffective track maintenance if such effects are not being investigated or inspected timely. This current study will fill this gab by establishing a new insight into nonlinear phenomena of combined short and long wavelength rail defects so that the *safety-critical* track inspection regime can be effectively adapted.

Initially, the detailed modelling of rail track dynamic and wheel-rail interaction was studied in 1992 while D-track program for dynamic simulation also have been created by Cai for his PhD's thesis of Queen's University in Canada [20]. Afterward, Iwnick has done a benchmark, which was called Manchester Benchmarks in 1998 [21]. In 2005; Steffens [22] has adopted the parameter of Manchester Benchmarks to compare performance of vary dynamic simulation programs and also developed the user-interface of D-track. On the other hand, D-track had still an issue of lower result than others and then the owner has revised the program after this benchmark. Subsequently, Leong has done the Benchmark II with the revised version of D-Track in 2007 [23].

In this present study, the dynamic simulation concept by Cai [20] has been adopted as seen in Figure 1 since the track model has included Timoshenko beam theory for rail and sleepers, which enable a more accurate behaviours of tracks. Note that rail cross section and sleeper pre-stressing are among the key influences on shear and rotational rigidities of Timoshenko beam behaviors in numerical modelling of railway tracks [24-27]. The irregularity of wheel and rail will cause higher dynamic impact force that the design condition level or serviceability limit state. The exceeing magnitude of the force generated by wheel and rail irregularities will damage track components and impair ride quality [28]. This study thus is the first to present the wheel-rail dynamic forces over both single defects and coupled defects. The dynamic amplification factor will be highlighted to identify the effect of train speeds. The scope of this study will be focused on ballasted railway tracks. The commonly used 106t freight wagons will be modeled and coupled with the discrete supported track model. The track model will be based on a standard rail gauge (1.435m). The outcome of this study will help railway organization in improving the predictive maintenance and inspection regimes.

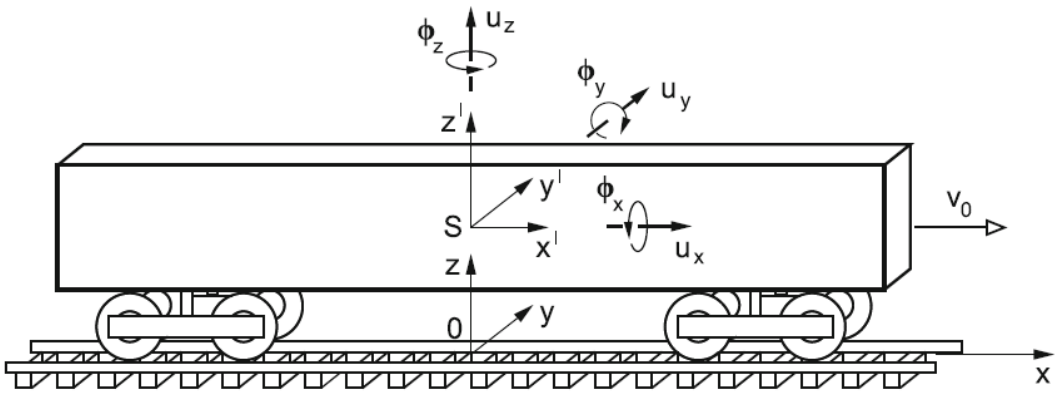

Figure 1: Coupling vehicle-track model [22]

2 DYNAMIC BEHAVIOURS

To design a ballasted railway track, it is important to assure safety and satisfy all the requirements of various stakeholders. The variety of dynamic loads from vehicle-track interaction and different environments make the rail infrastructure design highly complicated.

2.1 Dynamic wheel load

The dynamic loads induced by the vehicle moving on track structure will be considered as quasi-static force (equivalent to a static load times a factor) when the loads contain typically less than 10 Hz and is used to study behaviour of vehicle and design of the track foundation. In many cases, the perfect rail and wheel surfaces will be used to calculate of contact force and a factor (dynamic factor) to apply to the static wheel load and give a result for quasi static wheel load. The low-frequency load from a vehicle will apply to track geometry at a few cycles per second (up to 20 Hz).

In Australia, the most common method for calculation is presented by the Railway of Australia (ROA) manual or called "A Review of Track Design Procedures" or the "Blue Book". The Dynamic Impact Factor (DIF) from this method ignores vertical track elasticity. The dynamic vertical wheel load (PD) is expressed empirically as a function of the static wheel load (Ps) where Ø is the Dynamic impact factor (always ≥ 1). For example, PD = Ø Ps.

2.2 Eisenmann' Classical Formula

The Eisenmann formula is the most common method used for calculation the dynamic impact factor, used in a general track design. At the same time, the Eisenmann formula is modified by ROA and is used internationally. The Eisenmann formula (Eq. 1) and modified Eisenmann (Eq. 2) are shown respectively.

$$P_D = (1 + \delta\eta t) \cdot P_S \quad (1)$$

$$P_D = (1 + \delta\beta\eta t) \cdot P_S \quad (2)$$

where δ = Track condition factor; η = Speed factor, where η = 1 for speed (v) < 60 km/h and η = 1 + [(v-60)/140] for v > 60 km/h; t = Upper confidence level (UCL) factor; β = 1 for loaded vehicles; and 2 for unloaded vehicles.

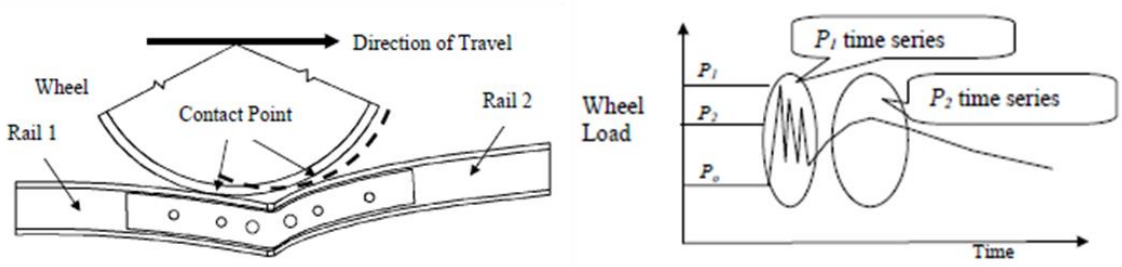

Figure 2: Impact force of wheel/rail contact at dipped rail joint [13]

2.3 Wheel trajectory over short wavelength rail defect

Dipped rail joint is termed to define the sum of an angle of dipped trajectory between each rail and the horizontal (in milli-radians). The two components of this angle consist of permanent deformation of the rail ends and the deflection of the joint under load. Jenkins et al. [29] described that the wheel travelling across a dipped rail joint creates the force peak as P1 and P2. The shape of the irregularity and characteristics of the vehicle create impact loading which the force at dipped joint increases almost linearly with the speed and angle of the dip. When the trains travelling at high speed approach a rail joint, the wheel lose will lose contact with the railhead of rail and land on the connected rail that generate the high dynamic impact force as illustrated in Figure 2.

The P1 force is a very high frequency (≅200 Hz -1000Hz) that is less than 0.5 millisecond in length (0.25 - 0.5 millisecond after crossing the joint). The compression of contact zone between wheel and rail create the inertia of rail and sleepers which does not directly transform to ballast or subgrade settlement. However, it has a significant effect on wheel/rail contact force. The P2 is occurred at a lower frequency range ((≅50 Hz -200Hz) than P1 occurring much later at typically 6 – 8 milliseconds. The unsprung mass and the rail/sleeper mass are moving down together influencing the compression of the ballast below the sleeper. P2 forces therefore increase the contact stresses and also induce the loads on sleepers and ballast. P2 force will be considered mostly by the track design engineer. Jenkins et al. [29] provided a method of calculation as follows:

$$P_1 = P_0 + (2\alpha v)\cdot\sqrt{\frac{k_H m_e}{1+m_e/m_u}} \tag{3}$$

$$P_2 = P_0 + (2\alpha v)\cdot\sqrt{\frac{M_u}{M_u+M_t}} \times\left[1-\frac{\pi C_t}{4\sqrt{K_t(M_u+M_t)}}\right]\times\sqrt{K_t M_u} \tag{4}$$

where: P_1 and P_2 = dynamic rail force (kN); P_0 = vehicle static single wheel load (kN); k_H = a chord stiffness to the Hertzian contact stiffness; m_e = the effective track mass (kg); m_u = the vehicle unsprung mass (kg); 2α = Total joint angle (rad); v = speed of vehicle (m/s); K_t = equivalent track stiffness (MN/m); M_t = equivalent track mass (kg); and C_t = Equivalent track damping (kNs/m).

2.4 Track settlement

Track settlement can cause the train passing the track with higher dynamic load increasing high-frequency variations to the ballast and subgrade. It will then cause non-elastic or plastic deformations with permanent setting. In normal situation, the track will generally not return to the same position but to the very close point (accumulated deformation). As time passes, all of non-elastic deformations will create a new track position and this phenomenon becomes

differential track settlement. The track alignment and surface level of track also change due to the accumulated non-elastic deformations. The irregularity of track will increase low-frequency oscillation of vehicle. However, the track settlement often takes place at the transition area to a bridge. In addition, the quality of ballast, sub-ballast and the subgrade are also the factor inducing permanent deformation [30-31].

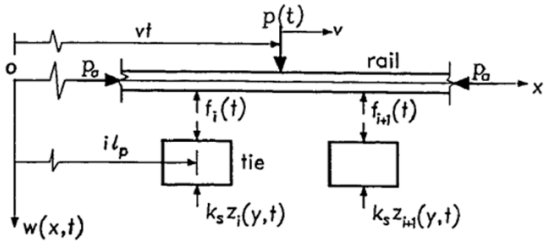
Track settlements typically consist of two phases. The first phase is after tamping that the gap between ballast particles is reduced quickly and so this layer is consolidated. The second phase is slower while the densification and inelastic behaviour of the ballast and subgrade materials are concerned as the two majors parameters influencing the ballast settlement that are the deviatoric stress, vibrations, degradation and subgrade stiffness. The empirical settlement equation for the substructure is shown below. It does only consider the ballast settlement not including subgrade settlement:

$$Z_{iN} = Z_{i0} + f\left(\log N, \sigma_{be}, I_{dyn}, I_{dec}, I_{Esub}\right) \tag{5}$$

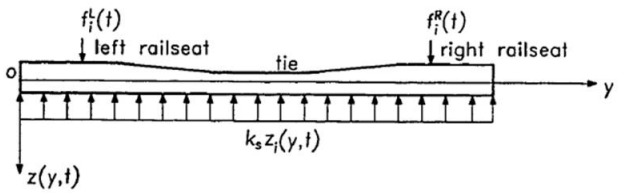
This equation describes the settlement of ballast below the sleeper *I* where: Z_{i0} = the given void amplitude; N = Number of load cycles; σ_{be} = the vertical equivalent stress in the ballast layer; I_{dyn}= the dynamic factor; I_{dec} = the degradation factor; and I_{Esub} = the subgrade stiffness factor.

3 COUPLING VEHICLE-TRACK MODELLING

The track model (D-Track) is simulated on Winkler foundation principal which only cross-section of track dynamic responses is considered symmetrically. Rail and sleeper were represented on elastic beam of either the Timoshenko type. The sleepers also support the rail as discrete rigid masses. Free-body diagram of track model are shown in the Figure 3(a) where *P(t)* is a moving wheel force at constant speed (v). Figure 3 (b) represents the force from rail to sleeper through the rail seat (i^{th}) and reaction force $k_s z_i(y,t)$ per unit length.

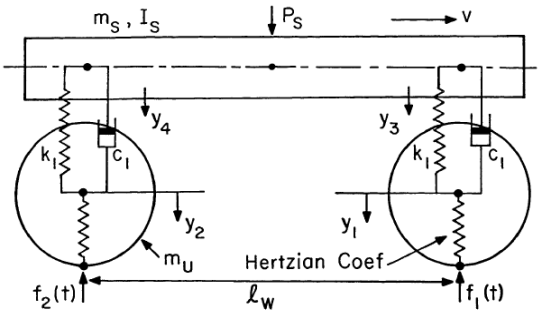


a) forces on the rail

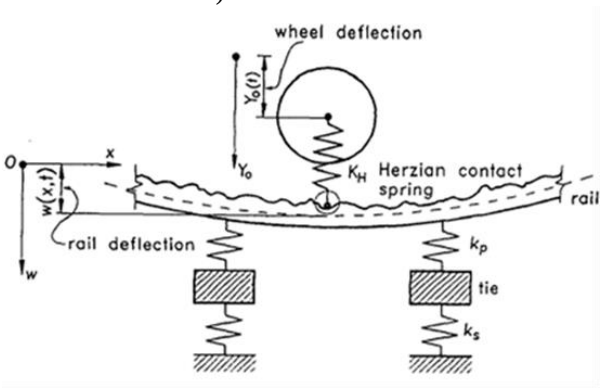


b) force on the sleeper

Figure 3: Free-body diagram of track model [22]



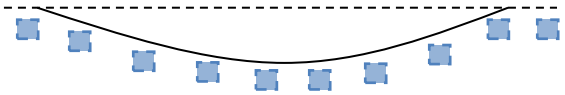
a) wheelset model



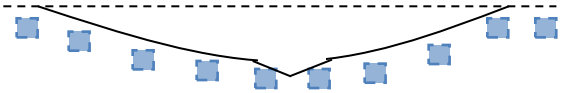
b) Herzian wheel-rail contact

Figure 4: Free-body diagram of vehicle-track model [22]

a) short wavelength



b) long wavelength



c) coupled short and long wavelength defects

Figure 5: Rail irregularity models

The wheelset model in this modelling consists of a four-degree of freedom which include of one bogie with two-axle, rail and track. The wheelset model uses the unsprung masses (mu) and the sideframe mass (ms, Is) to calculate on one rail through the primary suspension (k1, c1) as shown in Figure 4(a). The components of vehicles are demonstrated as a spring load by using Hertzian contact model. Moreover, the equations of motion in this model used the principles of Newton's law and beam vibration to apply. Integration between wheelset and track equations can be calculated by the non-linear Hertzian wheel-rail interaction model as illustrated in Figure 4 (b). The D-Track model has been benchmarked by [23, 24] in order to assess the accuracy and

verify the precision of numerical results. D-Track is thus adopted for this study. Rail surface profile irregularities can be esimated as inverse half-sinusoidal curve as shown in Figure 5(a). For track settlement, the study focus on a long span defect (such as large mud pumpting tracks) with a wavelength of 10m as shown in Figure 5(b).

4 RESULTS AND DISCUSSIONS

The numerical simulations have been carried out using 106t freight wagon with wheel radius of 0.46m and Hertzian spring constant of 0.87 x 10^{11} N/$m^{3/2}$. The dynamic wheel/rail contact forces can be seen in Figure 6.

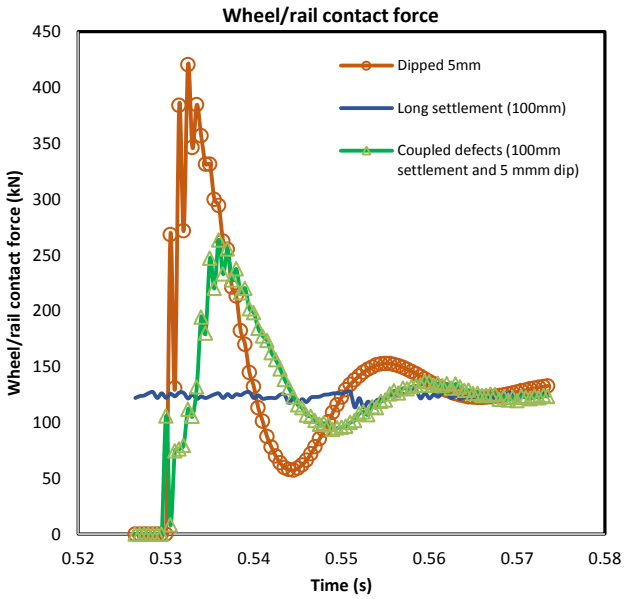


Figure 6: Wheel/rail contact force

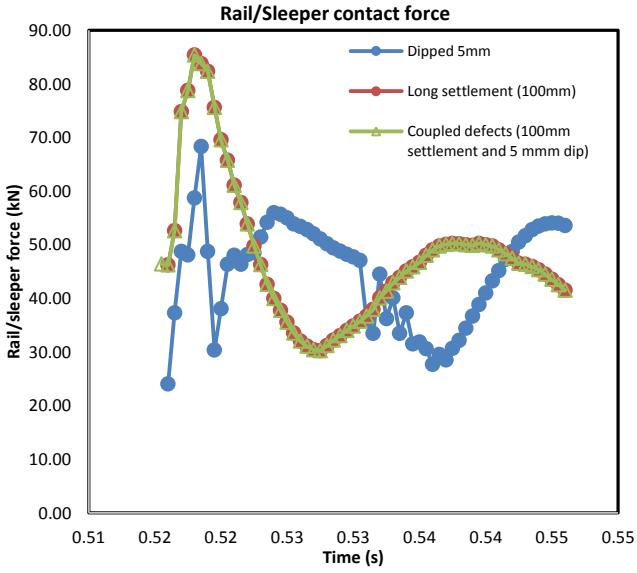

Figure7: Rail/sleeper contact force

Short wavelength defects have significant effects on the wheel/rail contact force in comparison with long wavelength defects. In contrast, surprisingly, it is apparent that long wavelength defect plays higher influence on the dynamic railseat loads (rail/sleeper contact) as shown in Figure 7.

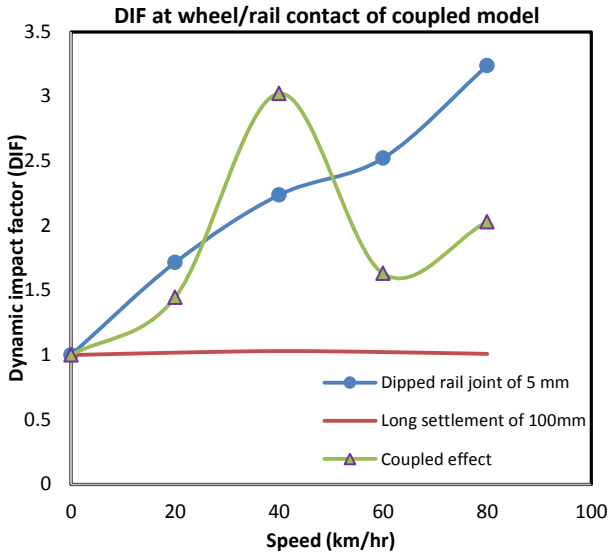

Figure 8: DIF at wheel/rail contact force

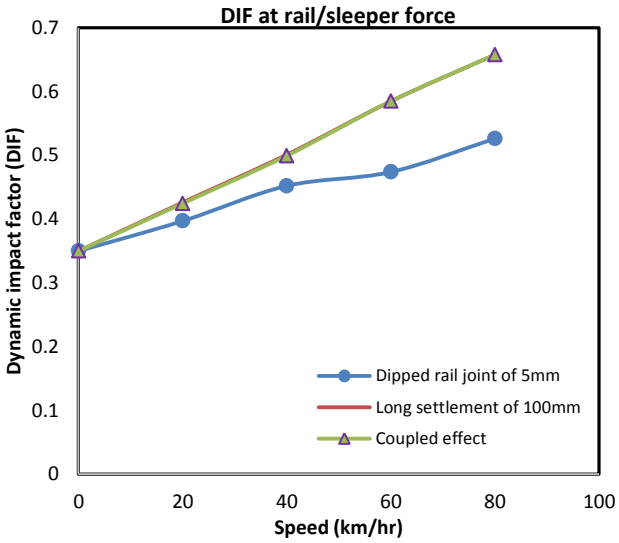

Figure 9: DIF at rail/sleeper contact force

The dynamic impact factor (DIF) can be evaluated from dynamic over static wheel force ratio. Figures 8 and 9 demonstrate the coupling dynamic vehicle-track interaction on contact forces and railseat loading conditions. It is clear that the coupling wheel/rail contact force is nonlinear (Figure 8) whilst rather liner relationships can be observed on the load sharing (Figure 9). It is clear that the individual short rail surface defects influence significantly the high frequency force at wheel/rail contact. However, the coupled short and long wavelength defects does not seem to play a strong influence on wheel/rail contact, but instead influence how the load is distribute on the sleepers.

5 CONCLUSION

This paper presents the nonlinear dynamic interactions between vehicle and track, which can cause vibrations and acoustic radiations to railway neighborhood. The nonlinear effects of coupled short and long wavelength rail defects on vehicle-track interaction have been highlighted. It is the first to evaluate the coupling dynamic vehicle-track interactions over coupled short and long wavelength rail defects. The results show that the coupled effect plays a key role on magnifying the rail/sleeper contact forces (railseat loads). The insight implies that sleepers will experience excessive dynamic loads and they can deteriorate and abrade at a relatively faster rate. More results on parametric effects of short and long wavelength as well as the effect of defect severity will appear elsewhere in the near future. This understanding into the nonlinear phenomena will help track engineers to manage and operate infrastructure assets more effectively.

Phase Field Material Point Method for Impact Induced Fracture

Emmanouil Kakouris*, Savvas Triantafyllou**

*Centre for Structural Engineering and Informatics, The University of Nottingham, **Centre for Structural Engineering and Informatics, The University of Nottingham

ABSTRACT

Predictive modelling of impact induced fracture is of extreme interest to the engineering community as it pertains to various applications, e.g., projectile impact and rocking of deformable medium. Dynamic failure mechanisms in brittle solids are governed by complex fracture phenomena such as crack initiation, multiple crack branching, or crack arrest. Mesh distortion errors that are inevitable in large displacement FEA hinder the fidelity of dynamic impact simulations where the deformability of the contact surfaces significantly affects the resulting contact forces and corresponding failure surfaces. Material point methods provide high fidelity solutions for large displacement and large deformation problems [1]. Rather than relying on the notion of a deforming mesh, material point methods introduce a particle based approximation for the deformable body that move within a non-deforming mesh. This introduces a considerable advantage as opposed to purely particle based methods as the continuum approximation is preserved thus releasing the requirement for high particle densities. To this point, material point implementations for brittle fracture have proven efficient in tackling quasi-static crack propagation in terms of computational simplicity and robustness. Phase Field Material Point Method (PF-MPM) has been successfully introduced [2] for quasi-static brittle fracture problems. In this, the phase field is resolved at material points and mapped onto grid nodes where the phase field governing equations are solved. PF-MPM has further been extended to account for surface energy densities with strongly anisotropy [3]. In this work, the PF-MPM is originally extended to account for dynamic brittle fracture within an anisotropic regime. Furthermore, a frictional contact framework is adopted to accurately capture the intriguing effects governing impact fracture problems. The phase field governing equations are solved independently for each contact body employing a predictor-corrector algorithm. The merits of the proposed scheme in tackling impact dynamics are investigated through a set of benchmark cases. [1] Sulsky D., Chen Z. and Schreyer H.L. (1994). Particle-based Flow Simulations for Complicated Viscous Fluid

Kazuhiko Kakuda*, Wataru Okaniwa**, Ituki Nishino***, Shinichiro Miura****

*Nihon University, **Nihon University, ***Nihon University, ****Nihon University

ABSTRACT

The numerical simulations of three-dimensional (3D) viscous fluid flows including multi-scale/physics and moving boundary/obstacle are indispensable in science and engineering fields from a practical point of view. Numerical difficulties have been experienced in the solution of the Navier-Stokes equations at higher Reynolds numbers. In particular, it is well known that the centered finite difference and standard Galerkin finite element formulations lead to spurious oscillatory solutions for flow problem at high Reynolds number regimes. To overcome such spurious oscillations, various upwind/upstream-based schemes have been significantly presented by many researchers in both frameworks. On the other hand, there are various gridless/meshless-based particle methods, such as SPH (Smoothed Particle Hydrodynamics) method[1], MPS (Moving Particle Semi-implicit) one[2], and PFEM (Particle Finite Element Method)[3] to simulate effectively such complicated flow problems. Recently, the physics-based computer simulations on the GPU (Graphics Processing Units) have increasingly become an important strategy for solving efficiently various problems, such as fluid dynamics, solid dynamics, and so forth. The purpose of this paper is to present the application of the GPU-based SPH/MPS method to 3D complicated fluid flow problems, namely the dam-breaking flow problem and the droplet-falling with surface tension. As the surface tension model, we adopt the inter-particle potential force with a potential coefficient. The problems of the dam-breaking flow and the droplet-falling with surface tension have been widely used to verify the applicability and validity of the numerical methods. The GPU-implementation consists mainly of the search for neighboring particles in the local grid cell using hash function for both methods. The MPS scheme is also applied to solve implicitly the Poisson equation with respect to the pressure fields by using GPU-based SCG (Scaled Conjugate Gradient) method. The workability and validity of the present approaches are compared with experimental data and other numerical ones. Data Analytics for Mining Process-Structure-Property Linkages for Hierarchical Materials

Surya Kalidindi*

*Georgia Tech

ABSTRACT

A majority of the materials employed in advanced technologies exhibit hierarchical internal structures with rich details at multiple length and/or structure scales (spanning from atomic to macroscale). Collectively, these features of the material internal structure are here referred to as the material structure, and constitute the central consideration in the development of new/improved hierarchical materials. Although the core connections between the material's structure, its evolution through various manufacturing processes, and its macroscale properties (or performance characteristics) in service are widely acknowledged to exist, establishing this fundamental knowledge base has proven effort-intensive, slow, and very expensive for most material systems being explored for advanced technology applications. The main impediment arises from lack of a broadly accepted framework for a rigorous quantification of the material's structure, and objective (automated) identification of the salient features that control the properties of interest. This presentation focuses on the development of data science algorithms and computationally efficient protocols capable of mining the essential linkages from large ensembles of materials datasets (both experimental and modeling), and building robust knowledge systems that can be readily accessed, searched, and shared by the broader community. The methods employed in this novel framework are based on digital representation of material's hierarchical internal structure, rigorous quantification of the material structure using n-point spatial correlations, objective (data-driven) dimensionality reduction of the material structure representation using data science approaches (e.g., principal component analyses), and formulation of reliable and robust process-structure-property linkages using various machine learning techniques. This new framework is illustrated through a number of case studies.

Modeling and Simulation of Magnetorheological Elastomers Filled with Magnetically Hard Particles

ABSTRACT

Magnetorheological elastomers (MREs) are a class of active composites which can alter their macroscopic properties if an external magnetic field is applied. Typically, these materials consist of a polymer matrix filled with micron-sized magnetically soft particles such as carbonyl iron. Another type of fillers are magnetically hard particles as NdFeB which exhibit significant magnetic hystereses effects. MREs with this kind of composition have features as field dependent coercivity and remanent magnetization which are typical for conventional magnetically hard materials. Recently published experiments [1, 2] indicate a significant influence of the effective hysteresis loops on the matrix stiffnes in such MREs. In this contribution we investigate the microstructural causes of this effect by the use of a computational modeling approach. The analyzed MREs are described by a microscopic model [2], i. e. the heterogeneous microstructure consisting of magnetizable inclusions embedded into a polymer matrix is taken into account explicitly. The constitutive models for the magnetizable particles and the polymer matrix are formulated separately. In order to describe the irreversible magnetic behavior of the NdFeB particles a thermodynamically consistent vector-hysteresis model based on [3] is used. The governing equations of the coupled magneto-mechanical problem are solved by a nonlinear finite element formulation [2]. Therein, the evolution equation of the hysteresis model is solved by means of an implicit integration scheme. In order to connect the macroscopic and the microscopic magnetic and mechanical quantities, a suitable computational homogenization scheme is applied [2]. The presented simulations indicate a rotation of the particles within the soft polymer matrix material. Due to this effect, the effective hystereses of the MRE are significantly smaller than the hystereses of pure NdFeB. The presented computational results are qualitatively in good agreement with the experiments discussed in [1]. References [1] J. M. Linke, D. Yu. Borin, S. Efficient and Reliable Simulation of Failure of Reinforced Concrete Structures under Impact (RTG 2250: Mineral-bonded Composites for Enhanced Structural Impact Safety)

Michael Kaliske*, Viktor Mechtcherine**, Aurel Qinami***, Alexander Fuchs****

*Institute for Structural Analysis, TU Dresden, **Institute of Construction Materials, TU Dresden, ***Institute for Structural Analysis, TU Dresden, ****Institute for Structural Analysis, TU Dresden

ABSTRACT

Existing concrete or reinforced concrete structures feature, as a rule, a relatively low resistance to various sorts of impact loading, such as shock, collision or explosion. The primary goal of Research Training Group 2250 (RTG 2250) is to bring substantial improvements in the impact-resistance of existing buildings by applying thin layers of strengthening material. By using in-novative, mineral-bonded composites, public safety and the reliability of vitally important infra-structure should be significantly enhanced. The scientific basis to be developed will additionally enable to build new, impact-resistant structures economically and ecologically. In order to elaborate a deep understanding of the specific structural behavior under impact loading, theoretical and numerical models extending far beyond current knowledge have to be developed. An important role is played by the simulation of the bond between the fibers and the matrix under very high strain rates as well as the development of relevant constitutive laws. For a realistic description of the macroscopic structural failure of strengthened concrete struc-tures under impact by an extended microplane model and by the discrete implementation of local damage by the eigenerosion approach, a large number of detail developments (material description at impact with microplane model for reinforced concrete and reinforcement layer, effective nonlocal description of extended inelasticity, formulation of eigenerosion for inelastici-ty) needs to be taken into account. Moreover, challenges in the combination of the methods (e.g. description of the wave propagation for the selected modelling) have to be overcome. The contribution introduces the RTG generally and elaborates on the simulation of structural behavior of this class of structures and loading cases.

ABSTRACT

X-ray diffraction (XRD) is a well-established experimental method for determining the dislocation density values in materials science, that helped developing basic models of crystal plasticity. To evaluate the X-ray line profiles measured on bulk samples the so called “strain broadening” setup is applied and the asymptotic properties of the X-ray intensity distributions are investigated with the momentum method [1]. The recently developed technique for investigating the statistical properties of dislocation structures by high resolution electron backscatter diffraction (HR-EBSD) enables us to calculate and examine the internal stress distribution in deformed crystalline materials. The application of the momentum method to HR-EBSD is a novel way to determine the total dislocation density [2]. The comparison of the two methods will be shown in the presentation to corroborate the results measured on copper single crystals. To explore the relevance and potential of the HR-EBSD-based evaluation method a 2D discrete dislocation dynamics simulation is applied [3]. The model establishes the understanding of the unexpected behaviour observed in the calculated HR-EBSD moments. It is also shown that the dislocation arrangement does not affect the tail of the probability distribution of the internal stress. The availability of spatially resolved stress maps opens further perspectives for the evaluation of correlation properties and mesoscale parameters of heterogeneous dislocation structures. [1] I. Variational Sea Ice Mechanics in the Regional Arctic System Model

Samy Kamal*, Andrew Roberts**, Elizabeth Hunke***, William Lipscomb****, Wieslaw Maslowski*****

*Naval Postgraduate School, **Naval Postgraduate School, ***Los Alamos National Laboratory, ****National Center or Atmospheric Research, *****Naval Postgraduate School

ABSTRACT

Since the 1970s, large-scale sea ice models have approximated compressive ice strength and mechanical thickening using empirical functions that modify the areal ice thickness distribution, g(h), under horizontal compression and shear. Yet, observational and modeling research since the 1980s has demonstrated that these empirical functions are flawed: compressive strength approximations that parameterize constant frictional loss relative to potential energy gain during ridging may perform no better than simple and unphysical estimates of ice strength. g(h) is itself a scale-dependent representation of sea ice thickness that should not be applied to models with resolution less than 10 km and it is missing the critical dimension of macro-porosity associated with fracture and fragmentation of individual ridges just a few meters across. Most importantly, empirical redistribution of g(h) overlooks the principle of stationary action as applied to non-conservative systems. Without considering the variational principles of ice mechanics, it is difficult to derive well-posed physics to represent ridging within the grid cells or elements of Eulerian or Lagrangian sea ice models, respectively, for horizontal resolutions of less than 1km to more than 50km. This work presents the first known application of variational sea ice ridging to a basin-scale coupled model – the Regional Arctic System Model (RASM) – that rectifies the problems highlighted above. Ridging statistics are computed by coarse-graining the degrees of freedom associated with individual ridge formation. Equations governing sea ice momentum and mass conservation have been derived using variational principles upwards from the scale of individual ridges, and therefore do not require empirical functions for sub-grid redistribution of sea ice thickness in our 9km model. Instead, the principle of virtual work determines the prevalence, shape, and porosity of ridges of different sizes that in turn ascertain the compressive strength of the pack within each model grid cell. This is achieved using an expanded state-space for the thickness distribution that includes macro-porosity. Results presented are objectively assessed against previous RASM simulations using both isotropic (EVP) and anisotropic (EAP) rheologies using freeboard skill scores obtained with an ICESat emulator.

Fast Level Set Topology Optimization by Means of a Sparse Hierarchical Data Structure

Sandilya Kambampati*, Carolina Jauregui**, Ken Museth***, Hyunsun Alica Kim****

*University of California San Diego, **University of California San Diego, ***Voxel Tech Inc., ****University of California San Diego

ABSTRACT

The application of level set methods for topology optimization offers several advantages, such as being able to handle complex topological changes and having an implicit definition of the dynamic boundary. However, a common criticism is that they tend to suffer in terms of computational efficiency when compared to the traditional topology optimization based on material distribution. We note that common level set topology optimization methods utilize dense (vs sparse) grid data structures, which significantly limits the memory efficiency and hence the available resolution of the dynamic interface. Another common numerical technique in the level set methods is the Fast Marching Method, which is an inherently a serial algorithm with a time complexity of O(NlogN) and does not easily parallelize. In this paper we demonstrate how the efficiency of level set methods for topology optimization can be substantially improved by employing the sparse data structure VDB [1], which is a hierarchical data structure that shares some of the performance characteristics of B+ trees traditionally used for high-performance file systems and relation data bases. As such VDB offers fast grid data access (average O(1)) and high grid resolutions with low memory footprints. We also employ more modern algorithms like the Fast Sweeping Methods, that has recently been parallelized for sparse grids and offers a superior time complexity of (N) [2]. Specifically we present benchmark studies of level set topology optimization. This includes discussions of the computational times and memory footprints of topology optimization based on the sparse VDB data structure as well as a reference implementation based on a dense grid. The efficiency and scalability of advection schemes used to update the level set method such as the inverse square distance interpolation, Fast Marching Method, and Fast Sweeping Method, will also be discussed. Crack Progress Analysis of Plain Concrete Using Prescribed Displacement Based on Hybrid-type Penalty Method

Atsushi Kambayashi*, Norio Takeuchi**, Yoshihiro Fujiwara***, Tadahiko Shiomi****

*Graduate School of Engineering and Design, Hosei University, **Graduate School of Engineering and Design, Hosei University, ***Mind Inc., ****Mind Inc.

ABSTRACT

Crack progress analysis of plain concrete using prescribed displacement based on hybrid-type penalty method Atsushi Kambayashi / Norio Takeuchi Graduate School of Engineering and Design, Hosei University Yoshihiro Fujiwara / Tadahiko Shiomi Mind Inc. We studied a new function of a crack opening utilizing the hybrid-type penalty method (HPM) developed by Takeuchi [1] to analyze the strength characteristics of the structural members of reinforced concrete structures. In fracture analysis, the measurement of crack mouth opening displacement (CMOD) is important because it is directly related to the fracture energy, Gf. The HPM can accurately assess the CMOD in discrete cracks at intersection boundaries between the subdomains of the HPM, thereby reflecting accurate fracture energy of the discrete cracks. Using the HPM, we simulated experimental tests conducted for a concrete structure and showed good qualitative and quantitative agreements between the simulated and the experimental results. [2]. Although most of analyses were conducted using load control method and satisfactory results were obtained only the region from continua to discontinua, deformation control method used to obtain further analysis such as softening phenomena. In this work, we introduced a new function for a prescribed displacement control with the HPM. This involved introducing an algorithm for the prescribed displacement in the rmin method [3], which is an incremental load method. The rmin method can accurately track tensile cracking and compressive failure in concrete structure. To validate the accuracy of the displacement control analysis with the new function, we conducted several analyses using uniform triangular mesh and Delaunay triangular mesh. And , we also simulated the three-point bending test for notched beams, which is a standard test of the plain concrete. Finally, we discuss the load-displacement relationship between the experimental tests and numerical results. References [1] N. Partially-Averaged Navier-Stokes Formulation of Two-Layer Turbulence Model

Chetna Kamble*, Sharath Girimaji**

*Texas A&M; University, **Texas A&M; University

ABSTRACT

Seamless transition between the Reynolds-Averaged Navier-Stokes (RANS) and Direct Numerical Simulation (DNS) is achieved by the Partially-Averaged Navier-Stokes (PANS) bridging strategy. In PANS, the physical resolution is controlled by filter widths which quantify the extent of partial averaging via the unresolved to total kinetic energy and dissipation ratios. This scale-resolving simulation method offers resolution of large scale turbulent structures at reasonable computational costs. In the present study, the PANS closure modeling is applied to a two-layer turbulence model which couples the standard k-epsilon model in the outer layer with a one-equation model in the near wall region. In RANS context, this turbulence model exhibits a superior near wall behavior compared to other near wall treatments. The PANS modified two-layer model aims to improve upon the near wall predictions by resolving the unsteady flow features of turbulence. The outer region in the PANS two-layer turbulence model is a PANS modified k-epsilon turbulence model, whereas, the inner layer comprises of a PANS modified one equation model of unresolved kinetic energy. The unresolved eddy viscosity and dissipation in the inner layer are specified in terms of unresolved kinetic energy and length scales. The effectiveness of the proposed PANS modified two-layer turbulence model is studied by a detailed comparison with a PANS k-omega turbulence model for a three-dimensional Channel flow for frictional Reynolds number, Retau = 180 and Retau = 590. The proposed model is assessed on the performance in reproducing the mean statistics, the turbulent flow quantities and the resolution of the turbulent flow structures. The PANS modified two-layer model displays improved accuracy in capturing the turbulent flow physics and thereby solidifying the effectiveness of the two-layer PANS scheme in the near wall region.

Isogeometric Analysis Using FEniCS

David Kamensky*, Yuri Bazilevs**

*University of California, San Diego, **University of California, San Diego

ABSTRACT

This talk introduces recent work on implementing extraction-based isogeometric analysis (IGA) [1] on top of the FEniCS open source finite element (FE) software project [2], while retaining many of the powerful features that make the latter an attractive analysis platform. We hopefully dispel the sentiment that FEniCS and IGA present conflicting visions for automating numerical solution of partial differential equations (PDEs). Several aspects of our implementation differ from the algorithms for Bézier extraction put forward by Borden et al. [3] in 2011, and our alternative approach may be useful for retrofitting other FE codes as well. A collection of object-oriented abstractions separate PDE solution from generation of extraction operators and thereby permit the use of a wide variety of spline types. We cover, as illustrative examples, the discretization of various PDEs that benefit from IGA and the use of T-splines imported from CAD software. We conclude by discussing possible future directions, and welcome input from the FE(niCS) and IGA communities. ABSTRACT

Fusion reactors have sophisticated detailed 3D geometries, especially in the SOL/antenna region, which their inclusion is crucial for a reliable simulation of fusion process. In this work, a fully automated parallel mesh infrastructure, PUMI1, that generates adapted curved meshes classified on the CAD model, is integrated in to a state-of-the-art plasma simulation solver2. This 3D edge plasma wave solver is implemented in the MFEM3 open source scalable C++ library that supports elements of different type i.e. H1 to L2 and order. To demonstrate the effect of the high-order geometry representation, a realistic detailed 3D CAD model of the antenna placed in the fusion chamber is chosen and the effect of the adapted curve mesh on the quality of the RF wave solution is studied. Efficient Numerical Solution of the Hydraulic Fracture Problem for Planar Cracks

Sergey Kanaun*

*Tecnológico de Monterrey, México

ABSTRACT

Efficient Numerical Solution of the Hydraulic Fracture Problem for Planar Cracks S. Kanaun Tecnológico de Monterrey, México An infinite elastic medium with a planar crack is considered. The crack is subjected to pressure of fluid injected inside the crack at a point of its surface. Description of the crack growth is based on the lubrication equation (local balance of the injected fluid and the crack volume), the elasticity equation for crack opening caused by fluid pressure, Poiseullie equation related the fluid flux with crack opening and the pressure gradient, and the criterion of crack propagation of linear fracture mechanics. The crack growth is simulated by a series of discrete steps. Each step consists of three stages: increasing the crack volume by a constant crack size, crack jump to a new size defined by the fracture criterion, and filling the new crack configuration by the fluid presented in the crack [1]. The problem is ill-posed and requires specific methods for numerical solution. The proposed method is based on an appropriate class of approximating functions for fluid pressure distributions on the crack surface and the theory of solution of ill-posed problems. It is shown that for small fluid viscosity, the three-parameter model of pressure distribution on the crack surface can be used [2]. The model allows one to satisfy the condition at the point of fluid injection, the balance equation of the volume of injected fluid and the crack volume, and fracture criterion at the crack edge. The analysis of evolution of the crack boundary is based on an original method of fast numerical solution of the integral equations of the crack problem of elasticity. The method allows constructing the crack boundary at discrete time moments for media with varying elastic properties and fracture toughness [3]. Evolution of the crack boundary in the process of fluid injection, time dependence of pressure distributions and crack openings are presented for examples of hydraulic fracture crack growth in layered heterogeneous media. Constraints Handling in Multi-Objective Evolutionary Algorithm by Two-Stage Non-Dominated Sorting Using Direct/ Neighborhood Mating for Multi-Disciplinary Optimization

Masahiro Kanazaki*, Minami Miyakawa**, Hiroyuki Sato***

*Tokyo Metropolitan University, **Hosei University, ***The University of Electro-Communications

ABSTRACT

A non-dominated sorting and dieted mating (TNSDM) is an operator to handle the constraint in evolutionary algorithms and authors have shown its applicability to real-world multi-disciplinary design problems with difficult-constraints. In original two-stage non-dominated sorting and dieted mating , parents are selected by non-dominated sorting based on constraint violation values and objective functions sequentially. NSGA-II with original TNSDM has achieved better performance than the well-known existent method. Extreme Pareto solutions, which are the end of the Pareto front and are equivalent to the optimum solution of the single objective problem, could not be acquired well only by the TSNDM. To overcome this problem, we developed a new method by introducing local mating in identical ranks in the TSNDM. We propose the expansion of TNSDM by adding neighborhood mating in identical ranks, and this is decided by non-dominated sorting. The proposed constrained handling method is employed in NSGA-II. We investigated the proposed approach by solving a test function and hybrid rocket design problem, a real-world problem. Each problem has six constraints. These problems are solved by the constrained NSGA-II, which is based on the simple penalty method, and the original TNSDM based NSGA-II. According to investigations, the proposed approach and TNSDM based optimizations acquire better Pareto front than the simple penalty based method does. In addition, the proposed method can acquire not only compromised solutions but also extreme Pareto solutions in good agreement with the TNSDM method. Comparing convergence history via hypervolume, the best performance also can be observed by the proposed method.

Dynamic Behaviour of Different Pulmonary Monocusp Valve Designs

Harkamaljot Kandail*, Marcelle Uiterwijk**, Jolanda Kluin***, Frans van de Vosse****, Carlijn Bouten*****, Anthal Smits******, Sandra Loerakker*******

*Eindhoven University of Technology, Netherlands, **Academic Medical Centre, University of Amsterdam, Netherlands, ***Academic Medical Centre, University of Amsterdam, Netherlands, ****Eindhoven University of Technology, Netherlands, *****Eindhoven University of Technology, Netherlands, ******Eindhoven University of Technology, Netherlands, *******Eindhoven University of Technology, Netherlands

ABSTRACT

Purpose: Right ventricular outflow tract in children with congenital heart diseases is often reconstructed with a transannular patch and a monocusp valve. However, there are no set standards for the monocusp valve design and as such, these designs vary from clinic to clinic. The aim of this investigation is to propose an optimal pulmonary monocusp valve design with physiologic opening and closing behaviour, good coaptation and minimal aortic regurgitation. Methods: Dynamics of a pulmonary monocusp valve which is currently under pre-clinical evaluation within 1Valve program, hereinafter referred to as PMV-1 valve, were simulated using finite element (FE) methods to optimise the monocusp design. A second hypothetical valve design was then proposed to overcome the limitations of PMV-1 valve and its dynamic behaviour was also simulated using FE methods. The native pulmonary artery was modelled as an anisotropic material using a Holzapfel-Gasser-Ogden model while the monocusp valves and transannular patches were modelled as isotropic Neo-Hookean hyperelastic materials. Valve dynamics were simulated by imposing the pressure difference between the right ventricle and the pulmonary artery on the ventricular side of the respective monocusp valve designs and all simulations were performed for three cardiac cycles. Results: Dynamics of PMV-1 valve from the FE model were compared with dynamics from an ex-vivo heart model and a good agreement between the numerical and experimental results was observed. PMV-1 valve was implanted in the pulmonary artery in the closed position and its free-edge was prone to folding when the monocusp valve opened during systole. During diastole, only an edge-based coaptation between the free-edge of PMV-1 valve and pulmonary artery was observed. Unlike the initial design, the proposed design of the second monocusp valve is meant to be implanted in the open position. FE results for the second monocusp valve predicted that the free-edge of this valve design does not fold during the entire cardiac cycle. Also, better coaptation was seen for this valve design as the coaptation length between the free-edge and pulmonary artery was approximately 2.1 mm. Conclusion and future work: FE results from this investigation suggest that it is desirable to implant the pulmonary monocusp valve in the open instead of the closed position to achieve physiologic valve dynamics. This is an ongoing research project and fluid-structure interaction simulations are currently being performed to quantify aortic regurgitation and the risk of thrombosis associated with each valve design.

Spectral Element Solutions for Heat Transfer Augmentation

Kento Kaneko*, Paul Fischer**

*UCIC, **UCIC

ABSTRACT

We consider spectral element based simulations of thermal transport to study heat transfer augmentation in pipe flow with wire coil inserts, which induce turbulence and a rotational mode. We compare our numerical results with available experimental data for three distinct coil geometries and several Reynolds numbers. Sevreral additional simulations were run to determine the change in the Nusselt number when the rotational mode is completely removed. Three cases have geometries with equally-spaced tori whose distance corresponds to the pitch in the coil cases and a fourth case has a meandering coil with no net helicity. We present Nusselt number vs. Reynolds number results for all of these cases and analyze the effectiveness of gradient-diffusion based models for prediction of mean thermal transport in these configurations.

ABSTRACT

Magnetic separation is one of the mineral processing technology. Its technology utilizes magnetic susceptibility of different substances to separate them. In conventional magnetic separation studies, a particle was assumed as a free particle composed of one component. On the other hand, in actual operations, feed particles usually consist of locked particles composed of some components. The efficiency of magnetic separation was affected by locked particles. To achieve high efficiency, it is necessary that locked particles are appropriately controlled in the magnetic separation. However, there has not been little knowledge about the magnetic force acting on locked particles and the behavior of the locked particles in magnetic separators. Therefore, it is important to model the magnetic force acting on locked particles in magnetic field. This study modeled the magnetic force acting on locked particles by the magnetic field analysis. This study assumed that locked particles composed of two components with different magnetic susceptibilities. The finite element method (FEM) was used to calculate the magnetic force acting on a locked particle. According to the FEM analysis on the different composition ratio of locked particles, it was introduced that the model formula of the relationship between the magnetic susceptibility and the composition ratio of locked particles in the magnetic field. The FEM analysis suggested that this model formula depended on distribution of components within particles. Based on the FEM analysis results, magnetic separation incorporating locked particles model was simulated. In this simulation, the behavior of locked particles was calculated by the discrete element method (DEM), and the magnetic field in a magnetic separator was calculated by the FEM. Using this simulation, it was analyzed that the relationship between the applied magnetic field and the efficiency of magnetic separation. Furthermore, the simulation result was compared with the experimental results. In the case of particles consisting of only flee particles, the simulation results qualitatively agreed with the experimental result. However, there was some quantitative difference between the simulation and experimental results. In the case of particles containing locked particles, the difference between the simulation and experimental results became smaller. As a result, it was suggested that the behavior of locked particles could be appropriately simulated by the locked particle model.

ABSTRACT

Fluid-structure interaction (FSI) is an important phenomenon in engineering because it often causes unexpected mechanical vibration and sometimes brings the structural destruction. Numerical simulation is effective for the research on the control of FSI because numerical simulation is proper for parametric study and can cut the cost of experiments. In our previous study [1], we proposed FSI analysis with active control, where both fluid and structural analyses were performed in detail, but specific models of actuators and sensors were not considered. It was assumed that the mass and volume of the actuators and sensors could be neglected and arbitrary control force could be given. It is necessary to introduce a specific model in order to put the previous analysis to practical use. For reducing the vibration caused by FSI, piezoelectric actuators and sensors are widely used because it has excellent electromechanical properties. For examples, flutter phenomenon which causes undesired vibration to the aircraft is diminished by using piezoelectric materials. In this study, we implement the model of piezoelectric materials to our previous system. In order to analyze strictly all the physics of piezoelectric materials, the host structure, and the surrounding fluid, we develop a general-purpose structure-fluid-electrostatic analysis system by integrating electrostatic analysis and partitioned iterative FSI analysis of the previous system. To find an optimal balance between accuracy and computational cost, we propose and verify three coupling approaches. In the first approach, structure-fluid-electrostatic analysis is split into electrostatic analysis and FSI analysis. The second approach splits into fluid analysis and structure-electrostatic analysis. The structure-electrostatic is solved by monolithic approach. In the third approach, electrostatic analysis is inserted into FSI iteration. In the present study, we investigate the stability of each system by simulating various control of FSI, and we compare three systems in the viewpoint of stability. A Study on Accuracy Improvement of Decomposed Surrogate Model with Random Samples for High Dimension Problem

Kyeonghwan Kang*, Ikjin Lee**

*KAIST (Korea Advanced Institute of Science and Technology), **KAIST (Korea Advanced Institute of Science and Technology)

ABSTRACT

Surrogate model has been widely used to solve engineering problems with heavy computation, and there have been many studies to generate surrogate model with limited samples due to the computation cost. However, practical surrogate model generating method dealing with high dimensional design space are still challenging. Among the approaches dealing with high dimensional surrogate model, decomposition is one of popular approach for its efficiency and flexibility. There are various approaches of decomposition, but accurate decomposition results require to generate samples not in the decomposed design space. Furthermore, there can exist random samples in practice engineering problem, but these samples are also difficult to be utilized in the decomposed surrogate model. In this study, the potential accuracy improvement method using the samples not in the decomposed design space is proposed. Previously unused samples are considered for approximation using Gaussian process and variable screening, and virtual samples are generated to improve the accuracy of each decomposed surrogate model. Numerical examples and engineering problem are used to check the performance of proposed method, and it is shown that the accuracy of the surrogate model is surely improved with random samples.

Topology Optimization with Manufacturing-related Constraints Expressed by Domain Integral of Level Set Function

Zhan Kang*, Yaguang Wang**, Pai Liu***

*Dalian University of Technology, China, **Dalian University of Technology, China, ***Dalian University of Technology, China

ABSTRACT

In topology optimization of continuum structures, certain geometrical constraints and interfacial behaviors, as well as uncertain geometrical manufacturing imperfections, are often of great importance to ensure the manufacturability or integrity of the structures. This talk will present some of our new developments on the study of manufacturing -related topology optimization problems in the level set function-based framework. The level set, as an implicit geometrical model, offers a natural description of shape and topology evolution and thus can be suitably used for representation of some geometrical constraints [1]. In our previous work, we proposed a unified integral-form constraint to avoid overlaps, to control the distances among the embedded objects in the topology optimization of multi-component structures [2]. Now we extend the idea of integral-form constraints to expression of other geometrical constraints to ensure the manufacturability of topology optimization results, including the casting constraint, the overhang angle constraint in additive manufacturing, and the shell-infill configuration description. All these constraints have explicit domain-integral forms, facilitating their sensitivity analysis with respect to shape variations. This approach inherits the properties of easier geometric information extraction of the implicit level set model. We also propose a level set-based implicit description model for modeling geometrical uncertainties arising from manufacturing errors. In particular, this model can mimic topological defects often exhibited by micro-size fabrication, which may result in breakage of load transmission paths of the optimized designs. Such a model is then combined with the uncertainty quantification techniques and employed in robust topology optimization considering random manufacturing errors. Exchange-correlation Potentials from Electron Densities Using a Complete Basis

Bikash Kanungo*, Vikram Gavini**

*Mechanical Engineering, University of Michigan, Ann Arbor, MI, **Mechanical Engineering, University of Michigan, Ann Arbor, MI

ABSTRACT

Exchange-correlation (xc) functionals, the cornerstone of the success of density functional theory (DFT), encapsulate the quantum many-electron interactions in terms of a mean-field. Although known to be unique functionals of the ground-state electronic charge density, n(r), the exact form of these functionals - expressed either as energy (Exc[n(r)]) or potential (Vxc[n(r)]) - are unknown, necessitating the use of approximate functionals. The existing xc functionals, despite their success in predicting wide range of materials properties, exhibit notable failures - under-predicted bandgaps, incorrect bond-dissociation curves, wrong charge-transfer excitations, to name a few. Typically, these approximations are constructed through semi-empirical parameter fitting in model systems, thereby making systematic improvement and conformity to certain known exact conditions difficult. We attempt to address this through data-driven modeling of xc functionals. This involves, generating a training data set comprising of n(r) to Vxc(r) map, and then, use of machine learning algorithms to learn the functional form of Vxc[n(r)] (and Exc[n(r)]), conforming to the exact conditions. In this work, we tackle the first step of generating the training data. To elaborate, it involves generating accurate n(r) from wavefunction-based calculations (e.g., quantum Monte-Carlo, full Configuration-Interaction), and then inverting the Kohn-Sham (KS) eigenvalue problem to obtain the Vxc(r) that yields the same n(r). We perform the inversion by posing it as a PDE-constrained optimization problem with Vxc(r) as the control variable and the KS eigenvalue problem as the PDE-constraint. We note that all previous attempts at this inverse problem have suffered from non-unique solutions or spurious oscillations in Vxc(r), both of which are attributed to the incompleteness of the Gaussian basis that was employed in the inversion. We resolve them by using spectral finite-elements - a complete basis - to discretize the problem. We employ limited-memory BFGS (a quasi-Newton solver) to solve the nonlinear optimization problem. Additionally, we make use of appropriate weights for the objective function to expedite convergence as well as to avoid ill-conditioning in the low density region. We validate the algorithm, to an accuracy of < 1 mHa, for cases where the densities are obtained from known xc functionals (LDA and GGA). Next, we demonstrate the capability of the algorithm for densities obtained from wavefunction-based calculations. Time permitting, we demonstrate preliminary results from simple regression techniques, that can faithfully generate bond-dissociation curves, using a few data points, thereby holding promise for future machine learning algorithms on the training data.

ABSTRACT

Renewable energy is a popular topic nowadays due to energy shortage. Especially wind energy converted by a wind turbine receives more attentions. In the present study, the blade design of the wind turbine using a couple method with computational fluid dynamics (CFD) and genetic algorithm (GA) is discussed. The blade shape is the most significant effective parameter in the wind energy conversion. Hence, we dedicated to utilizing an optimal method for the cross-sectional shape of blade, i.e., an airfoil, in order to get the better efficiency for producing the higher lift and lower drag to drive the wind turbine. According to the previous study, the Genetic Algorithm (GA) is known to be the robust method in the optimal design area. The Real-coded Genetic algorithm is considered because it can solve the defect of binary code. That is, the chromosomes length is too long to code. While the PARSEC parameterization method is used to represent the shape of airfoil through the eleven parameters as the control variables. Furthermore, a direct-forcing immersed boundary (DFIB) method is employed for simulations of interaction of rotating blades in a flow filed at moderate low Reynolds number. Numerical results reveal that the shape of airfoil can be optimized and the proposed DFIB model coupled with GA successfully simulates the moving blade in flow field for obtaining the high lift-drag ratio.

Investigating Strain Localization in Additively Manufactured Ti-alloys Using Detailed Material Characterization, Crystal Plasticity Finite Element Modeling and High Resolution Digital Image Correlation

Kartik Kapoor*, Todd Book**, Michael Sangid***

*Purdue Universirty, **Purdue University, ***Purdue University

ABSTRACT

Titanium alloys, produced via additive manufacturing techniques, offer tremendous benefits over conventional manufacturing processes such as reduction in production lead time and increased geometrical flexibility. However, there is inherent uncertainty associated with their material properties, often stemming from the variability in the manufacturing process itself along with the presence of residual stresses in the material, which prevents their use as critical components. The current work investigates Ti-6Al-4V, a dual phase Titanium alloy produced via direct metal laser sintering by carrying out crystal plasticity finite element (CPFE) simulations which models both the alpha and beta phases of the material explicitly and high-resolution digital image correlation (HR-DIC) on samples subject to cyclic loading. This is preceded by detailed material characterization using electron backscatter diffraction and back-scattered electron imaging whose results are utilized to create a realistic finite element microstructural mesh with spatial and crystallographic information about both the alpha and beta phases of the material. In addition, results from TEM studies, informing about distribution of the total dislocation density are utilized to inform the CPFE model itself. A method to incorporate the effect of grain-level residual stresses via geometrically necessary dislocations (GNDs) is developed and implemented within the CPFE framework. Using this approach, grain level information about residual stresses, in the form of GND densities obtained spatially over the region of interest, directly from the experimental material characterization, is utilized as an input to the model. Results indicate that the simulation strain maps show good match with those obtained using HR-DIC. In addition, possible sites for damage nucleation are identified, which correspond to regions of high plastic strain accumulation and occur near prior beta boundaries suggesting that prior beta boundaries play a critical role in strain localization. Further, a more robust method to incorporate residual stresses that involves modifying the elastic-plastic decomposition of the deformation gradient is proposed and implemented within the CPFE model. This is then tested with an available dataset of High-Energy Diffraction Microscopy experiments performed on Ti-alloys.

Fibrous Materials Characterization through a 3-D Fiber Network Model

Alp Karakoc*, Jouni Paltakari**, Eero Hiltunen***

*Aalto University, **Aalto University, ***Aalto University

ABSTRACT

The current work presents a 3-D fiber network model mimicking fibrous materials such as non-woven felt, paper and paperboards [1]. The objective is to investigate the effects of geometric properties and interactions of fibers on the overall stiffness and strength characteristics. In consideration to the objective, a stochastic micro-mechanical approach using random sequential adsorption was implemented to generate fiber geometries, alignments and positions in a confined space. Thereafter, material properties were assigned to each fibers and cohesive properties on the surface of each fiber intersection. Dirichlet boundary conditions were applied on the confined space and the problem was solved in explicit time integration scheme to determine the fiber network characteristics. The Elusive Granular Length Scale: Continuum vs Discrete

Konstantinos Karapiperis*, Jose Andrade**

*California Institute of Technology, **California Institute of Technology

ABSTRACT

Classical Cauchy continuum theories are known to be ill-posed after the onset of shear banding instability in granular materials. More elaborate continuum descriptions have provided a remedy by introducing a length scale, but have not enjoyed general acceptance due to the lack of a sound micromechanical basis. The renewed interest in such theories is largely due to grain-scale observations providing partial justification of the underlying assumptions. In this work, we provide a critical assessment of micropolar plasticity by comparing continuum predictions with grain-scale measurements in virtual triaxial experiments of real sands. Particularly, we employ the recently developed 3D Level-Set Discrete Element Method to shed light into the kinematics (rotational vortices) and kinetics (force chain buckling, couple stress) of shear bands obtained by means of advanced homogenization schemes. Upon identifying the major limitations of current theoretical models, we propose elements of an alternative framework possessing a direct physical interpretation of the granular length scale, towards the final goal of developing an enhanced multiscale theory.

1. INTRODUCTION AND MOTIVATION

Computational methods play an increasingly important role in modern engineering and scientific practice. Availability of high-performance computers along with the advanced (and easy-to-use) software, has enabled practitioners to successfully model complex physical, chemical and biological processes. For instance, fluid-structure interaction problems are some of the most challenging to efficiently model [1]. Irrespective of the problem, any large real-world computer modeling of engineering or scientific applications typically relies on partitioning (domain decomposition) of computational domain and parallel computing.

Domain partitioning (or domain decomposition) algorithms have become a popular approach to develop fast parallel solvers for various problems [2; 3]. In these algorithms, the spatial computational domain is split into a number of subdomains. This allows distribution of the computation among a pool of processors (CPUs and GPUs) available [4]. Obviously, such algorithms need some information (either primal or dual quantities) to be transferred across to adjacent subdomains. The domain partitioning can be either overlapping or non-overlapping. In general, the interface variables and compatibility of solution near the interface are defined implicitly.

In addition to work distribution among parallel processors, domain partitioning algorithms have other advantages. One can use different numerical formulations in different subdomains. Therefore, based on the nature of the process occurring at a particular subdomain, a suitable numerical formulation can be implemented to approximate the solution in the desired subdomain. A class of methods that offers such flexibility in terms of time-stepping (i.e., with different time-steps in different subdomains) is labeled *multi-time-step* or *sub-cycling* methods [6; 7]. Under this class of methods, the user can choose non-matching time-steps for time-integration in different subdomains. This feature is particularly of interest when a mix of implicit and explicit time-integration algorithms are used in different

subdomains [8; 9; 10]. In light of domain partitioning algorithms, multi-time-step methods can be of strong or weak types.

Weak multi-time-step algorithms rely on iterative approximation of variables in subdomains and their respective interfaces. These updated quantities are then used to advance the solution in other subdomains in time, which will in turn be used to update interface quantities. This iteration continues until desired convergence criteria are satisfied. This type of algorithm is extremely popular and forms the basis for many partitioned and multi-physics simulations. One of the main reasons why such algorithms are common is that the available (or legacy) solvers can be easily adopted in this approach, hence, accelerating the development phase. Some (but not all) of successful applications of weak algorithms can be found in [10; 11; 12]. Despite the attractive concept, weak partitioned algorithms are prone to numerical instability, especially in time-dependent problems. An alternative approach to multi-time-step simulation is to use strong coupling [13]. Unlike the weak algorithms, strong partitioning algorithms update the subdomain variables and the interface conditions monolithically. This means that iterations from one subdomain to another are not needed. These algorithms have better properties with respect to numerical stability. However, these algorithms are not as popular as the weak type. The reason being that development of software based on strong algorithms needs major modification to the existing computer codes. This hurdle translates into longer and more complicated development process. This drawback, however, has not stopped researchers to investigate strong multi-time-step algorithms. Some results in this area can be found in [14; 15; 16; 17].

This article is devoted to an overview of strong partitioning algorithms with non-matching time-steps. The theory and other aspects of these algorithms will be outlined. For the sake of presentation, we will limit our scope to elastodynamics problems. The rest of this paper is organized as follows: Section 2 is devoted to the theory and numerical formulation, Section 3 presents some numerical examples to demonstrate the discussed algorithms , and the conclusions are drawn in Section 4.

2. MATHEMATICAL MODELS AND NUMERICAL ALGORITHMS

2.1. Governing equations. Consider an open domain $\Omega \subset \mathbb{R}^{nd}$ and $\Gamma_D \cup \Gamma_N = \partial\Omega$. Boundary subsets Γ_D and Γ_N are mutually exclusive. The time-interval of interest is $\mathcal{I} = [0, T)$. The displacement field of the solid body, $\boldsymbol{u}$ defined in Ω, evolves according to conservation of linear momentum. We take the density of the solid to be ρ and the specific body force to be $\mathbf{b}$. The governing PDE can hence be written as:

$$\rho \frac{\partial^2 \boldsymbol{u}}{\partial t^2} = \operatorname{div}[\mathbf{T}] + \rho \mathbf{b} \qquad \boldsymbol{x} \in \Omega, t \in \mathcal{I} \tag{2.1a}$$

$$\boldsymbol{u} = \boldsymbol{u}_p \qquad \boldsymbol{x} \in \Gamma_D,\ t \in \mathcal{I} \tag{2.1b}$$

$$\mathbf{T}\widehat{\mathbf{n}} = \boldsymbol{t}_p \qquad \boldsymbol{x} \in \Gamma_N,\ t \in \mathcal{I} \tag{2.1c}$$

$$\boldsymbol{u} = \boldsymbol{u}_0 \qquad \boldsymbol{x} \in \Omega,\ t = 0 \tag{2.1d}$$

$$\frac{\partial \boldsymbol{u}}{\partial t} = \boldsymbol{v}_0 \qquad \boldsymbol{x} \in \Omega,\ t = 0 \tag{2.1e}$$

where $\boldsymbol{u}_p$ and $\boldsymbol{t}_p$ are prescribed values for displacement and traction on boundary. The initial displacement and velocity are shown as $\boldsymbol{u}_0$ and $\boldsymbol{v}_0$. The stress tensor is denoted by $\mathbf{T}$ and div[.] is the divergence operator. The stress tensor is related to the displacement field

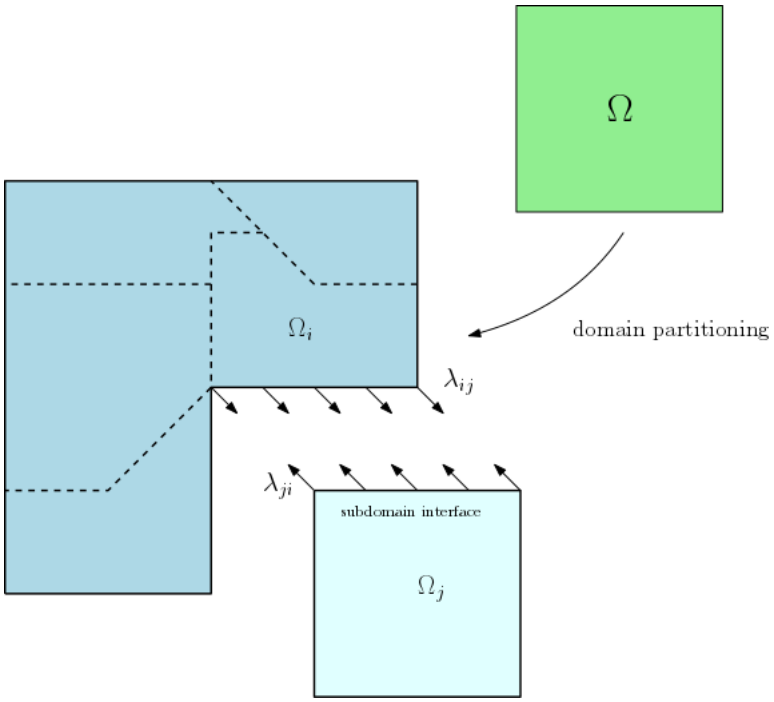

FIGURE 1. Domain partitioning of initial domain Ω into an arbitrary number of subdomains is shown (dashed lines show the interfaces between subdomains). Subdomains Ω_i and Ω_j share an interface (subdomain interface in the figure), where the Lagrange multipliers $\lambda_{ij} = -\lambda_{ji}$ are used to enforce compatibility of solution.

through a constitutive relation. For a more detailed account of constitutive models for solids and their finite element treatment, the reader can consult [18] and references therein.

In this paper, we are concerned with solving coupled PDEs of the form given in (2.1) on multiple subdomains that share interface with one another. Hence, in addition to the typical initial and boundary conditions given in (2.1), one needs constraints to ensure compatibility of the displacement fields at the interface of subdomains. As shown in figure 1, we will use Lagrange multipliers defined on subdomain interfaces to enforce an algebraic constraint of form

$$\boldsymbol{u}_i - \boldsymbol{u}_j = \mathbf{0} \tag{2.2}$$

on the interface of Ω_i and Ω_j (and all other neighboring subdomains). Subindices i and j indicate the respective subdomains. This equation, in addition to the conservation equation in (2.1) for each subdomain, completes the formulation of the problem on a partitioned domain. One can derive a weak form using a desired formalism (e.g., Galerkin) and discretize using the finite element methods.

2.2. Finite element discretization. Consider domain Ω partitioned into $\mathcal{S}$ non-overlapping subdomains. The boundary of each subdomain Ω_i is comprised of $\partial\Omega_i \cap \Gamma_D$, $\partial\Omega_i \cap \Gamma_N$ and $\widetilde{\Gamma}_i$. The part of boundary that is shared with other subdomains' boundaries is denoted by

$\widetilde{\Gamma}_i$. The function spaces needed for a FEM discretization of the problem at hand include

$$\mathcal{U}_i = \left\{ \boldsymbol{u}_i \in \left(H^1(\Omega_i)\right)^{nd} \middle| \boldsymbol{u}_i = \boldsymbol{u}_p \text{ on } \boldsymbol{x} \in \Gamma_D \cap \partial\Omega_i, \frac{\partial \boldsymbol{u}_i}{\partial t} \in \left(L^2(\Omega_i)\right)^{nd}, \frac{\partial^2 \boldsymbol{u}_i}{\partial t^2} \in \left(L^2(\Omega_i)\right)^{nd} \right\} \tag{2.3a}$$

$$\mathcal{W}_i = \left\{ \boldsymbol{w}_i \in \left(H^1(\Omega_i)\right)^{nd} \middle| \boldsymbol{w}_i = \boldsymbol{0} \text{ on } \boldsymbol{x} \in \Gamma_D \cap \partial\Omega_i \right\} \tag{2.3b}$$

for all subdomains $i = 1, \cdots, \mathcal{S}$. In addition, trace operators are needed that are defined on the subdomain interfaces

$$\mathcal{M} = \left\{ \boldsymbol{\mu} \in \left(H^{-1/2}(\bigcup_{i=1}^{\mathcal{S}} \widetilde{\Gamma}_i) \right)^{nd} \right\}. \tag{2.4}$$

Furthermore, the inner product on any subset K of Ω is defined as

$$(a, b)_K = \int_K a \cdot b \, \mathrm{d}\Omega, \tag{2.5}$$

with $a \in \mathcal{W}_i$ and $b \in \mathcal{U}_i$. Given these definitions, a weak form for the partitioned can be written on finite element e belonging to the triangulation (mesh) on subdomain i (i.e., $\forall \Omega_e \subset \mathcal{T}(\Omega_i)$, $i = 1, \cdots, \mathcal{S}$) as: find $\boldsymbol{u}_i \in \mathcal{U}_i$ and $\boldsymbol{\lambda} \in \mathcal{M}$, such that

$$\left(\boldsymbol{w}, \rho \frac{\partial^2 \boldsymbol{u}_i}{\partial t^2}\right)_{\Omega_e} = (\boldsymbol{w}, \boldsymbol{t}_p)_{\partial\Omega_e \cap \Gamma_N} + \left(\boldsymbol{w}, \mathrm{Sign}[\widetilde{\Gamma}_i]\boldsymbol{\lambda}\right)_{\partial\Omega_e \cap \widetilde{\Gamma}_i} - \left(\mathrm{grad}[\boldsymbol{w}^{\mathrm{T}}], \mathbf{T}\right)_{\Omega_e} + (\boldsymbol{w}, \rho \mathbf{b})_{\Omega_e} \quad \forall \boldsymbol{w} \in \mathcal{W}_i \tag{2.6a}$$

$$(\boldsymbol{\mu}, \boldsymbol{u}_i - \boldsymbol{u}_j)_{\widetilde{\Gamma}_i \cap \widetilde{\Gamma}_j} = 0 \quad i, j = 1, \cdots, \mathcal{S},\ i \neq j \text{ and } \widetilde{\Gamma}_i \cap \widetilde{\Gamma}_j \neq \varnothing \quad \forall \boldsymbol{\mu} \in \mathcal{M} \tag{2.6b}$$

where $\mathrm{Sign}[\Gamma_\mathrm{i}]$ is an arbitrary sign of $+1$ or -1 assigned to the subdomain interfaces such that

$$\mathrm{Sign}[\widetilde{\Gamma}_i \cap \widetilde{\Gamma}_j] = -\mathrm{Sign}[\widetilde{\Gamma}_j \cap \widetilde{\Gamma}_i]. \tag{2.7}$$

It should be noted that proper inf–sup conditions [19] need to be satisfied to ensure stability of this discretization. Finite element discretization results in a differential/algebraic equation [20] in terms of the nodal displacement values and the Lagrange multipliers as given below:

$$\mathbf{M}_i \ddot{\mathbf{u}}_i = \mathbf{f}\left(\dot{\mathbf{u}}_i, \mathbf{u}_i; t\right) + \mathbf{C}_i^{\mathrm{T}} \boldsymbol{\Lambda} \quad i = 1, \cdots, \mathcal{S} \tag{2.8a}$$

$$\sum_{i=1}^{\mathcal{S}} \mathbf{C}_i \mathbf{u}_i = \mathbf{0} \tag{2.8b}$$

where $\mathbf{M}_i$ and $\mathbf{u}_i$ are the mass matrix and nodal displacements, respectively. The vector of nodal Lagrange multipliers is denoted by $\boldsymbol{\Lambda}$ and $\mathbf{C}_i$ are the signed Boolean matrices (discretized trace operators). The superposed dots show differentiation with respect to time. Equation (2.8) is a differential/algebraic equation of index 3. This equation can be solved in a multitude of ways.

2.3. Algebraic interface constraint. Note that in a time-continuous setup, the algebraic constraint can be replaced by its derivatives given below

$$\sum_{i=1}^{\mathcal{S}} \mathbf{C}_i \mathbf{u}_i = \mathbf{0}, \ \sum_{i=1}^{\mathcal{S}} \mathbf{C}_i \dot{\mathbf{u}}_i = \mathbf{0}, \ \sum_{i=1}^{\mathcal{S}} \mathbf{C}_i \ddot{\mathbf{u}}_i = \mathbf{0} \tag{2.9}$$

However, the time discretization of equations (2.8) with either of the constraints given in (2.9) will indeed yield different numerical values (as it is expected). Also, enforcing one type of interface constraint (e.g., displacements or velocities) does not imply compatibility of the other kinematic variables at the subdomain interface [21]. This phenomena is known as *drift-off*, which refers to deviation of the numerical solution from the constraints manifold [20]. Hence, one of the main difficulties in developing numerical algorithms for differential/algebraic equations compared to purely differential equations is recognizing the drift-off in the numerical solution. Drift-off is usually not avoidable. Hence, various numerical methodologies for controlling this effect have been developed [22; 23].

A method for controlling the drift-off was proposed by Baumgarte in [24]. The motivation behind using the Baumgarte stabilization method is to control drift-off from the displacement, velocity and acceleration constraints. The Baumgarte stabilization method for the current problem reads as follows:

$$\sum_{i=1}^{\mathcal{S}} \mathbf{C}_i \ddot{\mathbf{u}}_i + \alpha_1 \sum_{i=1}^{\mathcal{S}} \mathbf{C}_i \dot{\mathbf{u}}_i + \alpha_2 \sum_{i=1}^{\mathcal{S}} \mathbf{C}_i \mathbf{u}_i = \mathbf{0} \tag{2.10}$$

where α_1 and α_2 are user-defined constants that control (supress) the values of drift-off. Note that the Baumgarte stabilization method is an efficient way of controlling the drift-off, as only one algebraic constraint (as a result only one Lagrange multiplier) is used. For comparison, the Gear-Gupta-Leimkuhler (GGL) methodology [21; 25; 26] requires more than one algebraic constraint (and consequently more than one Lagrange multiplier). Hence, the size of the problem is smaller and more suitable for computer simulations, especially in practical problems with a large number of subdomains. However, GGL method often provides better accuracy because the extra interface constraints are directly enforced.

In this article, Newmark time-integration methods will be used. Time discretization using the Newmark method [27] can be written as:

$$\mathbf{v}^{(n+1)} = \mathbf{v}^{(n)} + (1-\gamma)\Delta t \mathbf{a}^{(n)} + \gamma \Delta t \mathbf{a}^{(n+1)} \tag{2.11a}$$

$$\mathbf{d}^{(n+1)} = \mathbf{d}^{(n)} + \Delta t \mathbf{v}^{(n)} + \Delta t^2 (\frac{1}{2} - \beta)\mathbf{a}^{(n)} + \Delta t^2 \beta \mathbf{a}^{(n+1)} \tag{2.11b}$$

where Δt is the time-step, β and γ are time-integration parameters. The time-discretized values of displacement, velocity and acceleration are denoted by $\mathbf{d}$, $\mathbf{v}$ and $\mathbf{a}$, respectively. Note that with domain partitioning one can choose subdomain-specific time-steps and integration parameters. Having subdomain-specific parameters give the user the freedom to choose different members of the Newmark time-stepping family of algorithms for different subdomains. An important application of this feature is the implicit-explicit time-integration. The Newmark time-stepping algorithms (and its descendants) are well studies in numerical solution of second-order differential equations. Application of this class of methods to solution of differential algebraic equations (such as in equation (2.8)) is studied to a lesser extent. In the following section, we will explore the differences in the outcome of numerical simulations based on the type of interface constraint utilized.

3. NUMERICAL EXAMPLE

Consider a unit square domain agitated by a time-dependent force applied at the point $(0, 0)$ described as:

$$f(t) = e^{-t}\sin(t) \quad t \in [0, 5). \tag{3.1}$$

The boundaries on $x = 1$ and $y = 1$ are non-absorbing (Dirichlet-type) and the rest of the boundary is free. We will model propagation of a scalar wave over the domain by splitting it into three non-overlapping subdomains. In figure 2 the domain decomposition is shown. We will use linear triangular elements for finite element discretization. The speed of propagation in this medium is set to be $c_0 = 0.1$. The time-integration parameters in all subdomains will be $\beta = 1/4$ and $\gamma = 1/2$ (see (2.11)). The subdomain time-steps are set to $\Delta t_1 = 0.02$, $\Delta t_2 = 0.002$ and $\Delta t_3 = 0.002$. The system time-step is $\Delta t = 0.02$.

The interface compatibility criteria of interest will be the v-continuity method and the Baumgarte stabilization methods. In the v-continuity method, we will only enforce continuity of velocities near the interface. Constraints on compatibility of displacements and accelerations will not be enforced. In the Baumgarte stabilization method, as given in equation (2.10), a linear combination of displacement, velocity and acceleration values at the interface is set to zero. In this numerical illustration, we will choose $\alpha_1 = 2/\Delta t$ and $\alpha_2 = \sqrt{2}/\Delta t^2$.

The numerical values at time $t = 15$ are shown in figure 3. It can be seen that the difference in the two numerical results is about 0.1% of the values. In both cases of v-continuity and Baumgarte stabilization methods, the time-stepping parameters are exactly the same. Hence, the difference shown is only a result of interface compatibility conditions. Notably, the two methods give different values in energy as well. Figure 4 shows this quantity against time. This difference in energy, ΔE, at every time-step is defined as

$$\Delta E^n = |E^{(n)}_{\text{v-continuity}} - E^{(n)}_{\text{Baumgarte}}| \quad \forall n \tag{3.2}$$

which is the difference in energy based on the v-continuity and the Baumgarte stabilization method. As a result, one can conclude that the two methods have different numerical energy dissipation properties as well. This numerical example shows that the interface condition alone causes a deviation in the resulting numerical values.

4. CONCLUSION

With growing accessibility to computational capacity (such as cloud services, etc.) development of numerical algorithms designed to take full advantage of this architecture is more necessitated than ever before. A popular approach to distribution of work among a cluster of processors is the domain decomposition (domain partitioning) method. In this class of methods, the computational domain is split into several subdomains and the arrays associated with each subdomain can be manipulated by a few of the processors available, independently. The interface variables are used to enforce compatibility of numerical solution, and need to be transferred to other processors.

In this article, we overviewed the non-overlapping domain partitioning approach for a simple structural dynamics model. We looked into the mathematical theory of partitioned finite element discretization which results in differential/algebraic equations. Through a numerical example, two popular interface compatibility methods for partitioned algorithms were compared. Multi-time-step and strongly coupled time-integration algorithm was used

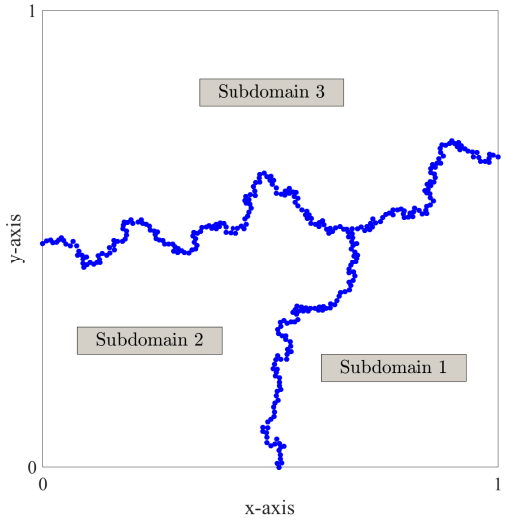

FIGURE 2. Partitioning of the computation domain into three non-overlapping subdomains.

to show how different subdomain interface conditions can affect the final numerical values. It was also shown that interface conditions lead to particular numerical energy dissipation characteristics. Based on the application, the user needs to identify the proper subdomain interface constraints to be used.

Squeeze-film Flow in the Presence of a Thin Anisotropic Porous Bed: an Application to Knee Joint

Timir Karmakar*, Raja Sekhar G. P.**

*Indian Institute of Technology Kharagpur, India, **Indian Institute of Technology Kharagpur, India

ABSTRACT

We consider a theoretical model of squeeze-film flow in the presence of a thin porous bed. It is assumed that a flat bearing is approaching towards the porous bed. The gap between the porous bed and the bearing is assumed to be filled with a Newtonian fluid. The liquid porous interface is assumed to be flat. Assuming that the fluid is Newtonian, we use Navier-Stokes equation in the fluid region and Darcy equation in the fluid saturated porous region. Lubrication approximation is used to the hydrodynamic equation of motion in the gap and in the porous region. We use Beavers & Joseph (1967) and Le Bars & Worster (2006) conditions at the liquid-porous interface and present a detailed analysis on the corresponding impact. We assume that the porous bed is anisotropic in nature with permeabilties K2 and K1 along the principal axes. Accordingly, the anisotropic angle ? is taken as the angle between the horizontal direction and the principal axis with permeability K2. We show that the anisotropic permeability ratio and the anisotropic angle make a significant influence on contact time, flux, velocity etc. The analysis is presented when a bearing approaches the porous bed for a given constant velocity or a given constant load is presented. We present some important findings relevant to knee joint based on the anisotropic of the human cartilage. The permeability of the articular cartilage depends on the proteoglycan matrix especially glycosaminoglycan (GAG) chains and the properties are influenced by the arrangement of the collagen fibres in different directions which form a anisotropic network of the human cartilage. In case of constant load, we have estimated the time duration a healthy human knee remains fluid lubricated. While in case of a constant velocity, we have estimated the load a human knee can sustain. 1. Physics Informed Deep Learning

George Karniadakis*

*Brown University

ABSTRACT

For more than two centuries, solutions of partial differential equations (PDEs) have been obtained either analytically or numerically based on well-behaved forcing and boundary conditions for well-posed problems. However, in real-life applications the available input data are often incomplete, noisy, and of variable fidelity, rendering existing computational methods ineffective. Moreover, despite the availability of big data in many domains, high-fidelity scientific data are small and expensive to obtain. We are changing this paradigm in a fundamental way by establishing an interface between probabilistic machine learning and PDEs that express known physical laws and constraints. We develop data-driven algorithms for general nonlinear PDEs using Gaussian processes and deep neural networks tailored to the corresponding integro-differential operators. The only observables are scarce and noisy multi-fidelity data for the forcing/solution, which could be scattered anywhere in the domain. We refer to these smart systems that encode the proper physical laws in their description as Physics-Informed Learning Machines (PILM). This work is based on work of Maziar Raissi and Paris Perdikaris.

On Nonlocal Theories: Mathematical Models and Computational Approaches

Anssi Karttunen*, J.N. Reddy**

*Aalto, **Texas A&M; University

ABSTRACT

Structural continuum theories require a proper treatment of the kinematic, kinetic, and constitutive issues accounting for possible sources of non-local and non-classical continuum mechanics concepts and solving associated boundary value problems. There is a wide range of theories, from higher gradient to truly nonlocal. These include, for example, strain gradient theories [1, 2], couple stress theories, Eringen's stress gradient theories [3], and micropolar theories [4] (the micropolar theory of elasticity includes an independent microrotation), and thermodynamically consistent structural theories. In this lecture, an overview of recent research on strain gradient, stress gradient, couple stress, micropolar, and thermodynamically consistent theories in developing the governing equations beams, plates, and sandwich structures will be presented and their computational aspects will be discussed. In addition, a graph-based finite element framework (GraFEA) suitable for the study of damage in brittle materials will be discussed [5]. Acknowledgements: The author is pleased to acknowledge the collaboration on non-local and non-classical mechanics with Arun Srinivasa (TAMU), and Karan Surana (KU), and Debasish Roy (IISc). Simulation and Auralization for Noise Using Virtual Reality Technology

Kazuo Kashiyama*

*Chuo University

ABSTRACT

The evaluation of noise is very important for planning and designing of various construction works in urban area. There have been presented a number of evaluation methods for noise simulation. Based on the frame of reference used, those methods can be classified into two categories: 1) Methods based on the geometrical acoustic theory and 2) Methods based on acoustic wave theory. Both methods have advantages and disadvantages. For the methods based on the geometrical acoustic theory, the CPU time is very short but the numerical accuracy is low comparing with the methods based on the acoustic wave theory. On the other hand, the method based on the acoustic wave theory gives accurate solutions but the simulation becomes a large scale simulation. In the conventional studies, the computed noise level is described by the visualization using computer graphic such as iso-surface. Although the visualization is a powerful tool to understand the distribution of noise, it is difficult to recognize the noise level intuitively. This paper presents noise evaluation systems based on acoustic wave theory using virtual reality technology. The system exposes to users the computed noise level with both the auditory information using sound source signal and the visual information using CG image. The CIP method using AMR and FEM are employed for the descretization of wave equation. The ambisonics based on the spherical surface function expansion is employed to realize the stereoscopic sound field using computational results and sound source data. We performed the observation to obtain the sound source data for the auralization. The present system is shown to be a useful tool for planning and designing tool for various construction works in urban area, and also for consensus building for designers and the local residents.

The Effect of Water on the Wrinkling Formation in Graphene, and the Interlayer Shear between Graphene Bilayers

Jatin Kashyap*, Dibakar Datta**

*New Jersey Institute of Technology, **New Jersey Institute of Technology

ABSTRACT

Graphene, a two-dimensional material, is the cynosure in nanotechnology with wide ranges of applications. Wrinkling, a ubiquitous phenomenon in graphene, severely weaken its performance. In some cases, however, wrinkling is advantageous such as hydrophobic surface, energy storage. Whether beneficial or not, it is crucial to understand the wrinkles formation mechanism in graphene. Experimental investigations suggest that during the growth process, because of the humid environment in the growth chamber, water diffuses into graphene and substrate and plays a significant role in the wrinkle formation in graphene. There is no systematic computation investigation at all to address this critical issue. We, therefore, performed molecular dynamics simulation to analyze this important phenomenon by considering a simplistic model with graphene on graphene substrate and diffused water inside. First, we consider the absence of water inside and observe the formation of bigger wrinkle due to the coalescence of initial small wrinkles. However, if the initial wrinkles have a very high angle, the final wrinkle formed after coalescence is too high to maintain its stability and collapses to form multifold graphene structure. Next, we consider the humidity effect. The configuration of final wrinkle structure is governed by the completion between bending energy of wrinkled graphene and the van der Waals (vdW) energy between graphene, substrate, and water in-between. At low initial angle (e.g., 6 degrees), condensation of diffused water dominates the final wrinkle structure. At the intermediate initial angle (e.g., 11 degrees), when only one water layer is present, the bending energy dominates. However, with the increase in water density, i.e., more water layer inside, condensation of water droplet governs the final structure. At higher initial angle (e.g., 21 degrees), bending energy dominates and regulates the final wrinkle configuration. With the increase in initial wrinkle angle, the width of the final wrinkle formed after coalescence decreases while the final height shows a reverse trend. We further investigated the effect of water in the interlayer shear of graphene bilayer. We notice when the water is absent in between the layers, the interlayer shear shows a symmetric trend and the maximum shear is around 60 MPa. However, the presence of water droplet significantly reduces the maximum shear. Our systematic computational analysis provides a deeper insight into the role of water in the wrinkling formation in graphene and the interlayer shear between graphene bilayers.

Material Design of Elastoplastic Media with Decoupling Multi-scale Analysis

Junji Kato*, Shun Ogawa**, Hiroya Hoshiba***, Takashi Kyoya****

*Tohoku University, **Tohoku University, ***Tohoku University, ****Tohoku University

ABSTRACT

The present study proposes material design of elastoplastic media in the framework of a decoupling multi-scale analysis. The objective function is to maximize the energy absorption capacity of macrostructure with a prescribed material volume in the microstructure. Isotropic von Mises elastoplastic material model is employed for the constituents of microstructure and the anisotropic Hill plasticity model is used for the macroscopic constitutive law. In the framework of the decoupling multi-scale analysis, material parameters in the Hill's material model are identified by solving the microscopic boundary value problems based on the finite element analysis. This process is called numerical material testing. In the topology optimization of microstructure, conventional SIMP approach is utilized and gradient-based method is employed. In this study, the methodology to obtain the accurate sensitivity with low computational costs is proposed, where the sensitivity of the incremental strain with respect to design variables can be eliminated using the return mapping algorithms. It is verified by a serious of numerical examples that the proposed method has a great potential to design elastoplastic media, especially advanced materials such as functional materials.

Strain Shielding in Femurs with an Implant

Yekutiel Katz*, Zohar Yosibash**

*Tel Aviv University, **Tel Aviv University

ABSTRACT

More than half a million hip replacement surgeries are performed annually in the US, and similarly in Europe. The inserted metallic prosthesis in these surgeries changes the femur's natural loading conditions, leading to bone remodeling and resorption. This phenomenon, commonly known as "stress shielding", leads to reduction of implant's mechanical stability and increases the risk of periprosthetic femoral fracture. Thirteen percent of hip replacement surgeries undergo a revision surgery within ten years [1]. Orthopedic surgeons usually choose a prothesis based on clinical outcome reports, statistical data and their personal experience. No scientific tool exists that may assist surgeons to determine the biomechanically optimal prosthesis for a specific patient. Finite element analyses may be used as such a tool. The first essential step must be their verification and experimental validation. Intact femurs mechanical response had already been shown to be well predicted by high-order finite element models based on patient-specific QCT scans [2]. The generation of finite element models representing implanted femurs followed by their experimental validation will be presented. The experiments were conducted on fresh frozen cadaver femurs, loaded in different configurations. Measurements were performed using the 'gold standard' strain gauges, and also novel methods as digital image correlation. Once the models were validated, they were used to compare the mechanical behavior before and after the implantation. To quantify the implant's performance, comparison of the strain fields was performed. Strains were addressed rather than stresses due to their stimulation of the biological remodeling mechanism [3]. Norms to quantify strain shielding will be suggested. Such norms my assist orthopedic surgeons to choose an optimal implant for the specific patient, from the vast available variety of implants. ABSTRACT

Fluid-structure interaction simulations where the solid bodies are undergoing larger deformations require special handling of the mesh motion for Arbitrarily Lagrangian-Eulerian (ALE) formulations. Such formulations are necessary when body-fitted meshes with certain characteristics, such as boundary layer resolution, are required to properly resolve the problem. This work presents an overset mesh method to accommodate such problems in which flexible bodies undergo large deformations, or where rigid translation modes of motion are present as well. To accommodate these motions of the bodies through the computational domain, an overset mesh enabled ALE formation for fluid flow is discretized with the hybridizable discontinuous Galerkin (HDG) finite element method. The overset mesh framework applied to the HDG method enables the deforming and translating dynamics meshes to maintain mesh quality without re-meshing. Verification and validation are presented along with an example calculation.

A Hybrid Quasicontinuum Method

Aditya Kavalur*, Woo Kyun Kim**

*University of Cincinnati, **University of Cincinnati

ABSTRACT

Quasicontinuum (QC) is a spatial multiscale method which approximates the potential energy of an atomistic system with reduced computational cost. Like other partitioned-domain approaches, QC divides the simulation domain into atomistic and continuum regions. A full-atomistic description is restricted only to the atomistic region with the continuum region adopting a finite element method-based coarse-graining scheme and a continuum constitutive relation called the Cauchy-Born (CB) rule. While the CB rule can capture the full-nonlinearity of the strain energy density in the continuum region, its computational cost is one order of magnitude higher than the linear elastic (LE) constitutive relation, which is adopted by other partitioned-domain methods. In this study we propose a novel hybrid QC method where CB and LE are combined to increase the efficiency of the original QC method. The extension consists of two main steps. First, the continuum region is further divided into sub-domains such that the CB rule is applied only to those sub-regions adjoining the atomistic region with the energy of the remaining continuum region being approximated using the linear elastic constitutive relation. Second, a corrective force term is added as dead load to the nodes in the LE region in order to retain the higher order accuracy. Two test examples of Lomer dislocations and nanoindentation are employed to validate the proposed method. The simulation results reveal that the hybrid method is numerically more efficient than the original QC method while maintaining virtually the same accuracy.

Design of Cultivation Environment Scenario of Oryza sativa L.

E. Kawabe*, S. Nishiuchi**, E. Kita***

*Nagoya University, **Nagoya University, ***Nagoya University

ABSTRACT

While Japanese agriculture is high productivity, farmers are aging. Once the skillful farmers are retired, their knowledge should be lost. The aim of this study is to design the cultivation environment scenario of Oryza sativa L. “Koshihikari”. If the optimized scenario is obtained, the newcomers can do like the skillful farmers. The yield and the quality data in the rice cultivation and the environment scenario are collected by Agricultural Research Center of each prefecture and Japan Meteorological Agency, respectively. The prediction models of the yield and the quality of the Oryza sativa L. are defined by the multiple regression analysis or neural network analysis of the rice cultivation data (yield and quality) and the environment scenario such as average temperature, maximum temperature, minimum temperature, precipitation, hours of sunlight and diurnal temperature range. The objective function of the optimization problem is defined so as to maximize the yield and the quality of the Oryza sativa L. Design variables are composed of the part of the environment scenario variables such as maximum and minimum temperatures. Constraint conditions for the design variables are the upper and the lower bounds of the temperatures. Optimization problem is solved by L-BFGS-B method. The initial temperature fluctuation is the average year temperature in Nagoya. The optimized year temperature is considerably lower and then, very similar to that in Tadami. References [1] L. *Toyo University, **Nagoya University, ***Toyo University, ****The University of Tokyo, *****The University of Tokyo

ABSTRACT

Exa-scale supercomputers will appear around 2020–2022. To obtain high intra-node performance, e?cient utilization of processor cache memory should be considered. The traditional memory access-intensive approach, which prefers less computing and more storage on main memory, might not be e?ective for supercomputers in near future. The Domain Decomposition Method (DDM) is one of the e?ective parallel ?nite element schemes. We have been developing an FE-based parallel structural analysis code, ADVENTURE Solid, based on DDM, with the Balancing Domain Decomposition (BDD) pre-conditioners. The re-design of the subdomain local FE solver part, which is a performance sensitive kernel in the DDM code, is required. Here in this work, an “on-cache” iterative solver based on the DDM framework is developed. The subdomain local FE solver of the DDM code is implemented using CG solvers with element-by-element matrix storage-free approaches. These iterative solvers are parallelized using OpenMP, so that each subdomain can be solved by multiple cores. By adjusting the subdomain size so that the footprint ?ts within the last-level cache of a processor, this DDM code can be considered as a kind of an “on-cache” iterative solver”. Performance benchmark results are shown on various kinds of HPC platform having many core scalar processors, such as Skylake Xeon, Knights Landing and Fujitsu PRIMEHPC FX100.

Effect of Strain Path on Microstructure and Texture Inhomogeneity during Accumulative Angular Drawing Process of Ti-6Al-4V

Jakub Kawalko*, Krzysztof Muszka**, Piotr Bala***, Marcin Kwiecien****, Paulina Lisiecka-Graca*****, Maciej Szymula******

*AGH University of Science and Technology, Academic Centre for Materials and Nanotechnology, **AGH University of Science and Technology, Faculty of Metals Engineering and Industrial Computer Science, ***AGH University of Science and Technology, Academic Centre for Materials and Nanotechnology, ****AGH University of Science and Technology, Faculty of Metals Engineering and Industrial Computer Science, *****AGH University of Science and Technology, Faculty of Metals Engineering and Industrial Computer Science, ******AGH University of Science and Technology, Faculty of Metals Engineering and Industrial Computer Science

ABSTRACT

Accumulative Angular Drawing (AAD) process is a novel method used to produce wires with controlled inhomogeneity of microstructure and properties. Similarly to Severe Plastic Deformation (SPD) processes, it introduces high accumulation of deformation energy in the cross-section of the drawn wire and enables activation of additional deformation mechanisms compared to conventional drawing processes. In the current work, AAD process will be applied to produce wires made of Ti-6Al-4V alloy. This alloy is characterized by a limited ductility at room temperature due to hexagonal closed packed (HCP) structure. During AAD process strain path changes occur, what besides reduction of the cross-section area, introduces additional bending, shearing, burnishing and torsion to the deformed wires, and thanks to that, activates additional slip planes allowing successful realization of deformation process. In the present work, level of inhomogeneity of microstructure, texture and properties resulting from applied strain path history will be assessed. Conclusions regarding interrelationships between deformation history and resulting microstructural changes will be drawn in the light of possible texture mechanisms that are activated during AAD process. Due to a number of process parameters that affect the microstructural inhomogeneity, acquired data can be used for the numerical modeling. Understanding of the AAD of Ti alloys the with the aid from computer simulation will enable optimization of the process towards better control of microstructure and texture inhomogeneity what, in turn, will allow production of titanium wires with controlled gradual changes in their microstructure and properties.

SEISMIC RESPONSE CONTROL FOR EQUIPMENT WITH CASTERS USING SWITCHING WHEEL LOCK CONDITIONS

Key words: Seismic Response Control, Caster Wagon, Furniture, Rocking, Sliding, Numerical Analysis

Abstract. When an earthquake occurs, the people in and/or contents of buildings may suffer damage due to the sliding or overturning of furniture and equipment or the falling of objects even if the structure of the building experiences no damage. In this study, using numerical analyses, we investigate a model of effective equipment caster wheel control to reduce damage caused by the moving and overturning of equipment during earthquakes and propose a control method to switch the lock and free conditions of the caster wheel. In the numerical analyses, a simulator library of three-dimensional rigid body dynamics is used and two-direction earthquake ground motion is input into a model of a 10-story steel frame building. The horizontal displacement and the falling down of the equipment model are expressed depending on the caster lock condition.

1 INTRODUCTION

In an earthquake event, to protect people in a building, we need to consider not only the damage to a building's structure but also the damage caused by furniture in the building. When an earthquake occurs, furniture in a building and/or their contents may hit people or may overturn and hinder evacuations, as reported in the 2011 Great East Japan Earthquake. In particular, the seismic resistance of medical equipment is important because it affects whether medical activities can be performed following an earthquake. Most medical equipment are equipped with casters for convenience, and in the case of the 1995 Hyogo-ken Nanbu Earthquake, it was reported that medical equipment with high centers of gravity overturned when the casters were locked and moved around and collided with other equipment and the walls when the casters were not locked. Nikfar and Konstantinidis [1] estimated the seismic responses of hospital equipment supported by casters. They determined the frictional resistance of the casters, evaluated the seismic response of the equipment, and performed shaking table experiments. Kamada et al. [2] proposed an earthquake response control of caster-supported wagons using an ER, variable-type brake and demonstrate its effectiveness via simulations and excitation

experiments. In past studies of furniture earthquake response analyses, it has been common to use a spring–mass model; however, this model does not consider the shape of the structure. Saomoto and Yoshimi [3] analyzed furniture earthquake responses using a physics engine, the Open Dynamics Engine (ODE) and performed numerical analyses considering the shape of the furniture. Masatsuki and Midorikawa [4] quantitatively examined the fluctuations of large displacements considering the collisions of multiple pieces of furniture and walls using a physical simulator, Springhead2. Isobe et al. [5] developed an effective numerical code based on the adaptively shifted integration (ASI)–Gauss technique for analyzing the motion of furniture subjected to seismic excitations.

In this study, using an ODE numerical analysis, we investigate effective caster wheel control to reduce damage due to equipment moving and overturning during earthquakes and propose a control method to switch the lock and free conditions of the caster wheels.

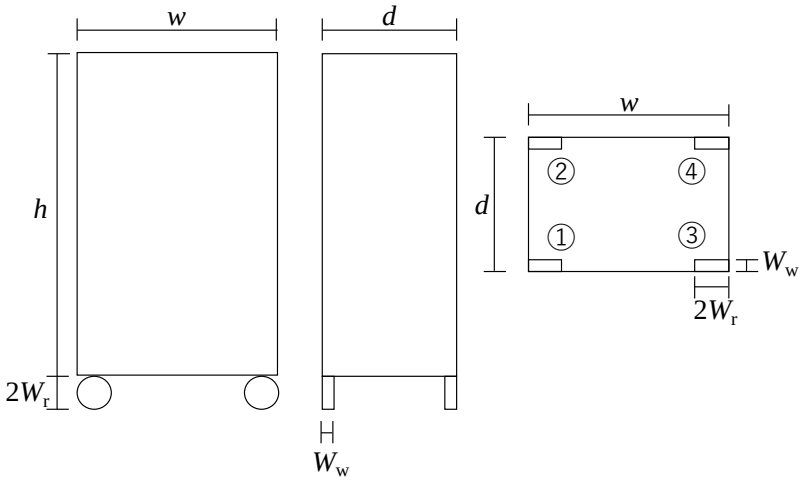
2 OUTLINE OF THE SIMULATION AND CASTER CONTROL METHOD

In the numerical analysis, we use ODE, which is a simulator library of three-dimensional rigid body dynamics. The modeled equipment with casters consists of a box and four wheels. The width, depth, height, and mass of the model are 0.45 m, 0.30 m, 0.80 m, and 10 kg, respectively. First, we input the two-direction earthquake ground motion (NS and EW) into a model of a 10-story steel frame building with a first natural period of 0.8 s and obtained the acceleration response time history on the top (9^{th}) floor. We assumed that the equipment is placed on the top floor of the building and input the response acceleration waves to the floor slab to obtain the response time history of the equipment model. We compared the responses for the following three caster conditions: (1) setting the casters as locked, (2) setting the casters as free, and (3) switching the casters between locked and free at constant time intervals.

2.1 THE EQUIPMENT MODEL

In this study, we consider the equipment model shown in Figure 1 and define the variables as shown in Table 1. The value obtained in the experiment conducted by Saito et al. [6] is used as the friction coefficient.

We name the casters as shown in Figure 1(c). In addition, for the sake of simplicity, the caster swivels do not rotate and are fixed at the position shown in Figure 1.



(a) Side view (b) Front view (c) Bottom view

Figure 1. The equipment model.

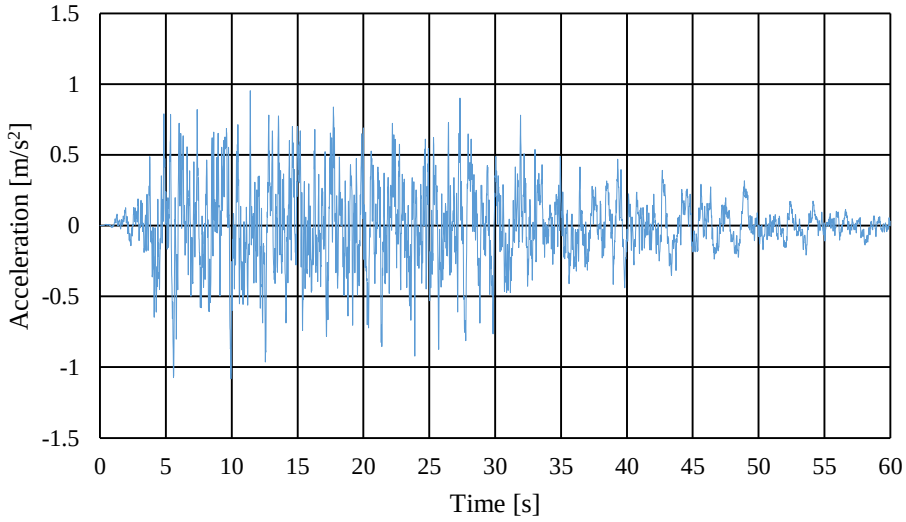
Table 1. Parameters of the equipment with casters.

Specification	Variable	Value
Equipment width	w	0.40 m
Equipment depth	d	0.30 m
Equipment height	h	0.80 m
Equipment mass	M	10 kg
Caster mass	M_c	0.05 kg
Caster wheel radius	W_r	0.0375 m
Caster wheel width	W_w	0.75 m
Friction coefficient when the casters are locked	μ_0	0.3
Static friction coefficient	μ_s	0.4
Friction coefficient when the casters are released	μ_{free}	0.02

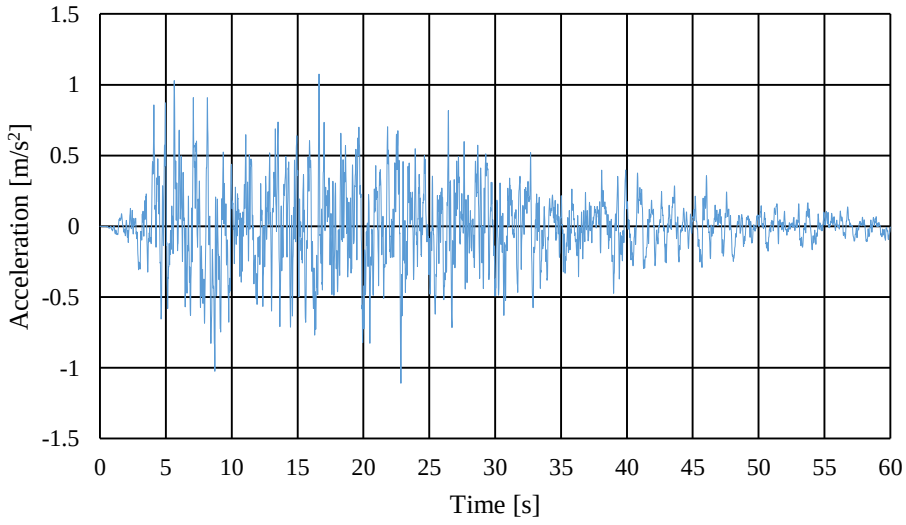
2.2 DYNAMIC ANALYSIS OF A BUILDING MODEL

With respect to the input ground motions, we use simulated ground motions of "rare earthquake ground motion" at an outcrop engineering bedrock with random phase components, as prescribed in Notification No. 1461 of the Ministry of Construction, Japan, May 31, 2000. The ground motions correspond to a return period of approximately 50 years. Figure 2 shows the

time history of the input ground acceleration, and Figure 3 shows the target acceleration spectrum and acceleration response spectra of the input waves.



(a) EW direction



(b) NS direction

Figure 2. Time history of the ground acceleration input to a 10-story building model.

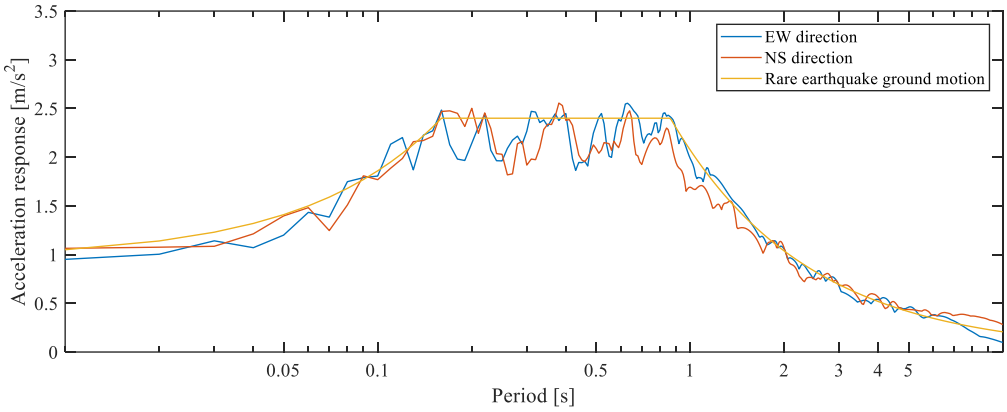


Figure 3. Target acceleration response spectrum of the rare earthquake ground motion and those of the input waves (5% damping).

We enter these input acceleration waves into the building model and obtained the acceleration response for each floor. We use the Newmark β method for the time history response analysis. With respect to the behavior of the specimen from a previous study by Purvance et al. [7], we consider the influence of the input wave in the vertical direction to be small. Therefore, in this analysis, we only input the horizontal acceleration waves and obtained the horizontal acceleration response of the building. The results of the time history response analysis for the 9th floor are shown in Figure 4, and Figure 5 shows the floor response spectrum on the 9th floor.

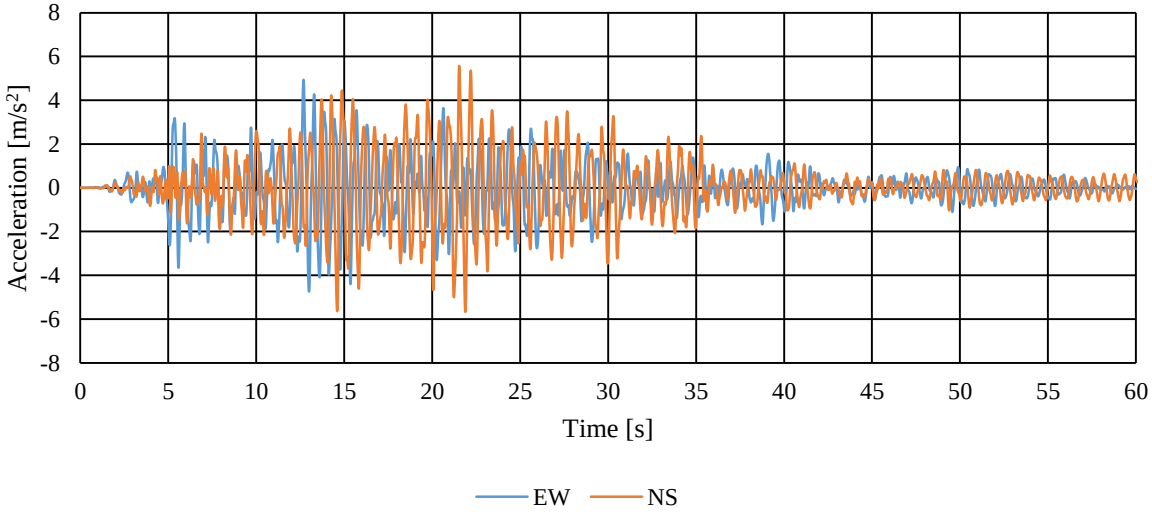

Figure 4. The results of the time history acceleration response analysis for the 9th floor of the building model.

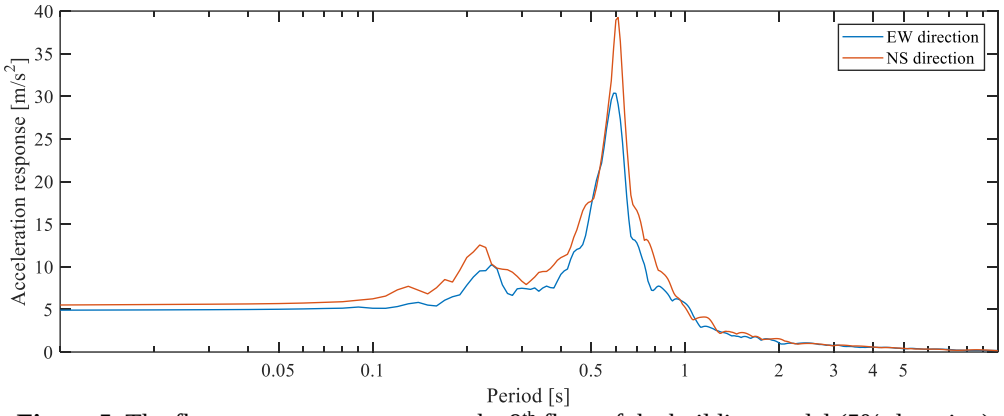

Figure 5. The floor response spectrum on the 9th floor of the building model (5% damping).

3 NUMERICAL ANALYSIS OF THE EQUIPMENT RESPONSE

3.1 ANALYSIS CONDITIONS

In the numerical analysis of equipment response, we set the time step to 0.01 s and the number of analysis steps to 6000. When a floor responds to the earthquake and the equipment model vibrates, the position and posture of the equipment change. Therefore, we consider the following 10 patterns for the possible posture of the equipment as shown in Table 2.

Table 2. The posture of the equipment.

Case	Condition
(a)	The case when all casters touch the floor.
(b1)	The case when casters 1 and 2 touch the floor.
(b2)	The case when casters 3 and 4 touch the floor.
(b3)	The case when casters 1 and 3 touch the floor.
(b4)	The case when casters 2 and 4 touch the floor.
(c1)	The case when only caster 1 touches the floor.
(c2)	The case when only caster 2 touches the floor.
(c3)	The case when only caster 3 touches the floor.
(c4)	The case when only caster 4 touches the floor.
(d)	The case when the equipment jumps and none of the casters touch the floor.

For the sake of simplicity, we assume the following.

- Only the inertial force and the frictional force are applied to the equipment.

- The inertial force is applied to the center of gravity of the equipment box model and the four casters of the equipment model.
- The equipment model is a rigid body and the casters do not swing or roll.
- After the equipment model falls down, we assume that the equipment does not move anymore.
- We consider the equipment model to have fallen when part of the upper surface of the equipment model touches the ground.
- We consider both static and dynamic friction forces.
- The angular velocity and angular acceleration are obtained from the rotation angle via the finite difference method.
- We assume that the normal forces of each caster wheel are equal. They are actually different; however, what matters is the resultant of the normal forces. There is no difference in the movement of the equipment model if these forces are assumed to be equal.

First, we consider the case when the caster i is locked. The frictional force vector $\boldsymbol{F}_{\mathrm{frc},i}$ is defined as

$$\boldsymbol{F}_{\mathrm{frc},i} = \begin{cases} -\boldsymbol{F} & \left(|\boldsymbol{F}| < \sum_{i=1}^{4} F_{\mathrm{s},i} \wedge \dot{\boldsymbol{x}}_i = 0\right) \\ -\mu_0 N_i \times \left(\dfrac{\dot{\boldsymbol{x}}_i}{|\dot{\boldsymbol{x}}_i|}\right) & \left(\left(|\boldsymbol{F}| \geq \sum_{i=1}^{4} F_{\mathrm{s},i} \wedge \dot{\boldsymbol{x}}_i = 0\right) \vee \dot{\boldsymbol{x}}_i \neq 0\right) \end{cases}, \tag{1}$$

$$F_{\mathrm{s},i} = \mu_{\mathrm{s}} N_i, \tag{2}$$

where $\boldsymbol{F}$ is the inertial force vector applied at the center of gravity of an equipment model, $F_{\mathrm{s},i}$ is the maximum static friction force calculated at the caster i, μ_0 is the static frictional coefficient, μ_{s} is the dynamic friction coefficient, N_i is the normal force at the wheel of caster i, $\boldsymbol{x}_i$ is the displacement of caster i, and $\dot{\boldsymbol{x}}_i$ is the velocity of caster i. The friction force is applied to the position where the casters touch the ground.

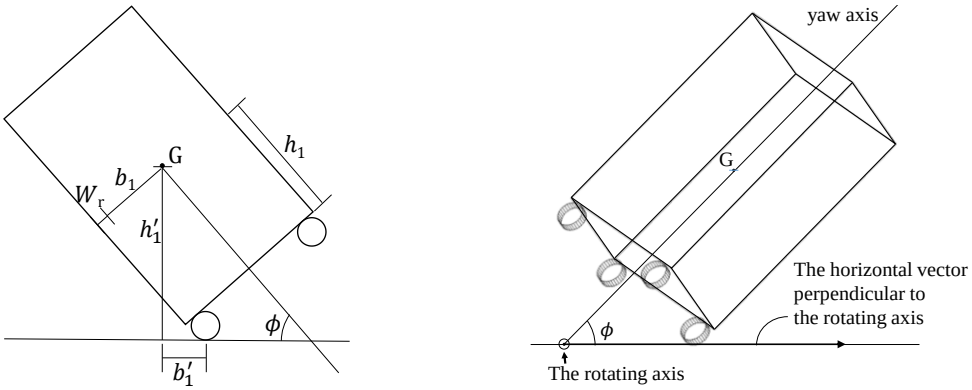
Di Egidio and Contento [8] defined the normal force N_i using a formula balancing the horizontal direction, the vertical direction, and rotation such that

$$N_i = m\left(g + b_1'\ddot{\theta} - h_1'\dot{\theta}^2\right), \tag{3}$$

where m is the mass of the equipment model and g is the gravitational acceleration. Suppose ϕ is defined by the angle between the yaw axis of a rigid body and the horizontal vector perpendicular to its rotating axis, then θ is calculated such that $\theta = \frac{\pi}{2} - \phi$. b_1' is the distance between the projected point of the center of gravity on xy-plane and the position where the casters touch the floor, and h_1' is the height of the center of gravity of the equipment model. In the cases (b1) and (b2), $b_1'$and h_1' are shown in Figure 6 and are described as

$$b_1' = h_1 \cos\theta - b_1 \sin\theta + W_r \cos\theta, \quad (4)$$
$$h_1' = h_1 \sin\theta + b_1 \cos\theta + W_r(1 + \sin\theta). \quad (5)$$

where b_1 is the difference between a half of the equipment width w and the caster wheel radius W_r, and h_1 is a half height of the equipment height h.



(a) The definitions of b_1' and h_1' in the cases (b1) and (b2) (b) The definition of ϕ

Figure 6. The definitions of parameters

Next, we consider the case when the casters are released. In addition to the friction force when the casters are locked, we apply an external force vector $\boldsymbol{F}_{\text{free}}$, which is equivalent to the casters rolling and is expressed as

$$\boldsymbol{F}_{\text{free}} = (\mu_0 - \mu_{\text{free}}) N \boldsymbol{r}, \quad (6)$$

where μ_{free} is the dynamic friction coefficient when the casters are rolling and $\boldsymbol{r}$ is the direction in which the casters are rolling. When θ is greater than $\frac{\pi}{4}$, the caster wheel rolls inward, and when θ is smaller than $\frac{\pi}{4}$, the caster wheel rolls outward. As with the friction force, the external force vector $\boldsymbol{F}_{\text{free}}$ is applied to the position where casters touch the ground.

3.2 FLOW DIAGRAM OF THE NUMERICAL ANALYSIS

A flow diagram of the numerical analysis is shown in Figure 7; the variables are defined in Table 3.

Table 3. The variables for the flow diagram in Figure 7.

Parameter	Explanation
t	The current step number
Δt	The time step width (= 0.01 s)
Flg_{fd}	If 1, the equipment model has fallen down, and if 0, it has not.
flg_{lk}	If 1, the caster wheels are locked, and if 0, they are not.

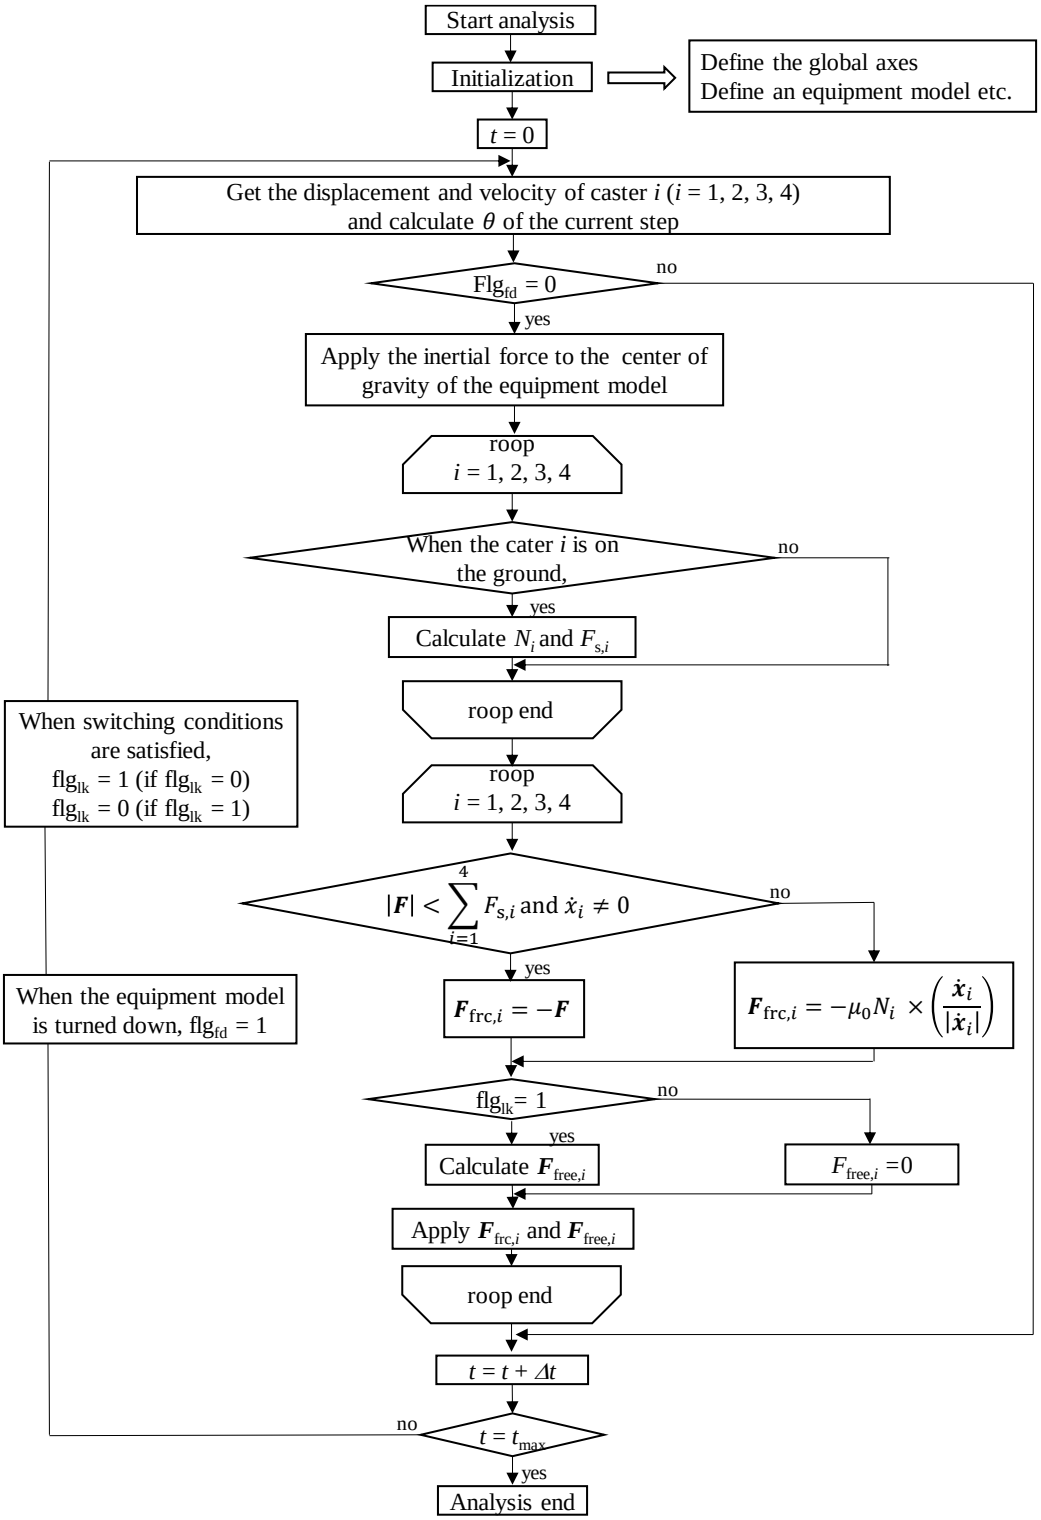


Figure 7. Flow of the numerous analysis.

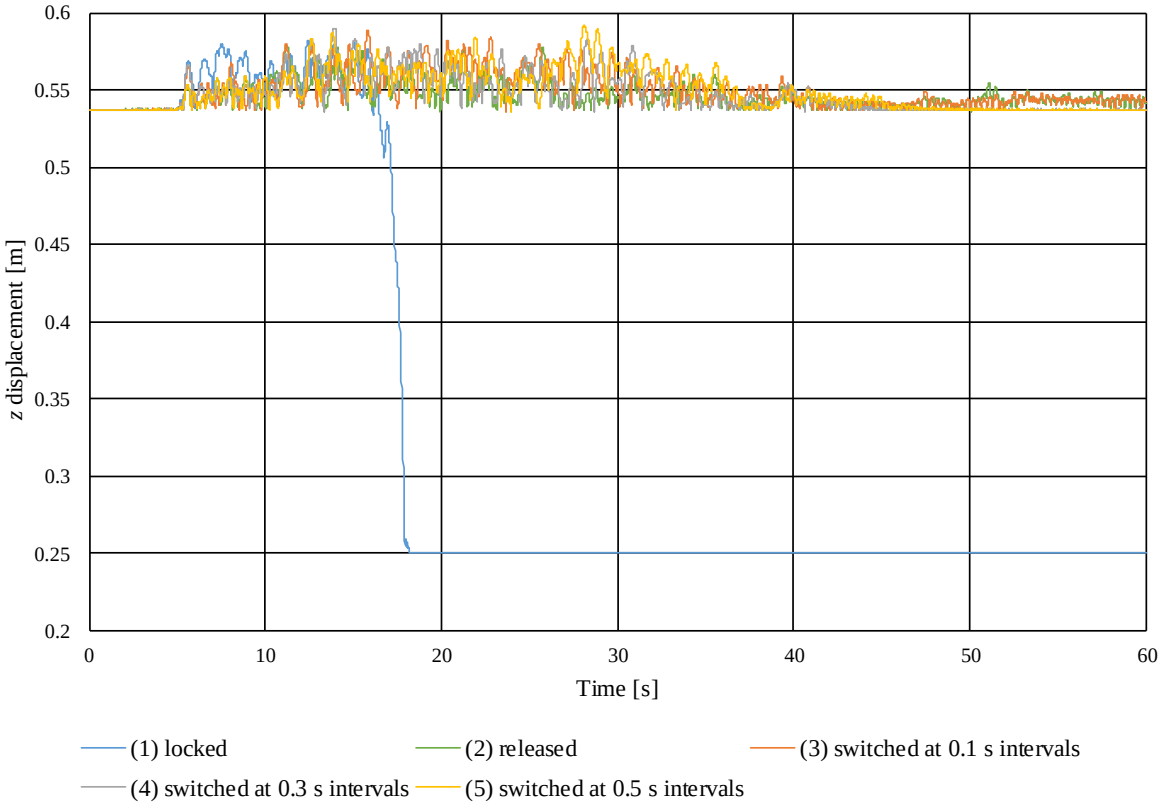
3.3 CONTROL OF THE CASTERS

We consider the following five conditions to control the casters.

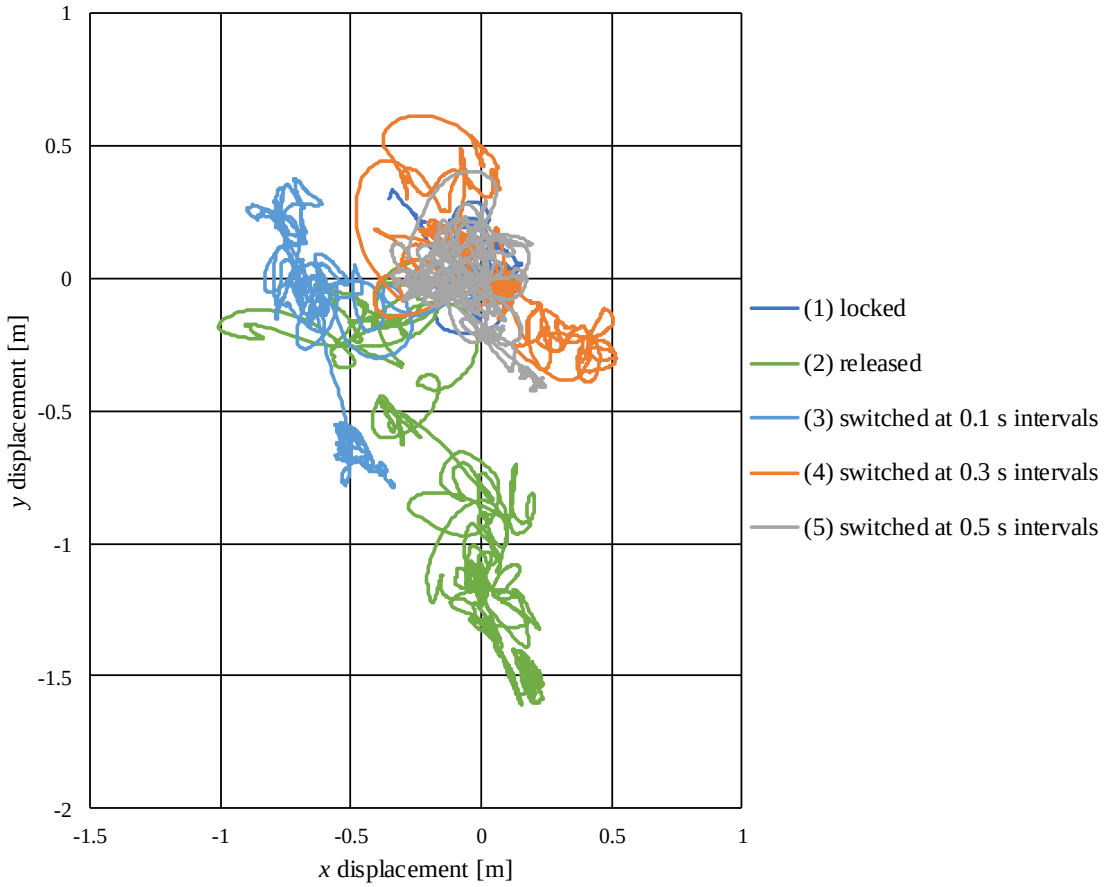
(1) All casters locked.
(2) All casters released.
(3) All casters switched between locked and released at 0.1 s intervals.
(4) All casters switched between locked and released at 0.3 s intervals.
(5) All casters switched between locked and released at 0.5 s intervals.

The results of the equipment time history response analysis with control patterns (1)–(5) are shown in Figure 8.



(a) *z* displacement of the center of gravity of the equipment model

Figure 8. The results of the equipment time history response analysis for the five control patterns.



(b) *x* and *y* displacements of the center of gravity of the equipment model

Figure 8. The results of the equipment time history response analysis for the five control patterns (continued).

From the *z* displacement of the center of gravity of the equipment model in Figure 8(a), the equipment model fell down only for condition (5), and from the *x* and *y* displacement of the center of gravity of the equipment in Figure 8(b), the equipment model moved to the farthest for condition (5) and moved the least for condition (4). Condition (3) resulted in a pattern where the displacement was small and the equipment did not fall down. We found that the caster switching control affects the behavior of the equipment model during seismic excitation. Therefore, caster switching control could reduce the damage in a building. However, more precise control methods need to be investigated.

4 CONCLUSIONS

We developed a simulation code to analyze the behavior of equipment with casters in a building and analyzed the motion of such equipment subjected to earthquake excitation. As a result of the numerical analysis, we confirmed that the proposed switching control could reduce the displacement and the probability of the equipment overturning. In a future study, we will derive

the overturning condition of furniture with casters from large amounts of damping control data, we will propose an optimal fixed/non-fixed switching control based on that condition, and we will perform shaking table experiments to validate our simulation results.

ACKNOWLEDGEMENTS

This work was supported by JSPS KAKENHI Grant Number 16H04455. The authors acknowledge Ms. Arisa Sugimoto for her contribution to fundamental formulation of control scheme.

PROBLEM-SOLVING ENVIRONMENT (PSE) IN COMPUTATIONAL ENGINEERING AND SCIENCE

SHIGEO KAWATA*

* Graduate School of Eng., Utsunomiya University
Yohtoh 7-1-2, Utsunomiya 321-8585, Japan
kwt@cc.utsunomiya-u.ac.jp

Key Words: Problem Solving Environment, Computer assisted computations, Scientific simulation, e-Science, PSE, Uncertainty in scientific computing.

Abstract. In this paper a review is presented on the PSE (Problem Solving Environment) concept in computational engineering and science. In the PSE concept, human concentrates on target problems and works out solutions, and a part of application of solutions, which can be solved mechanically, is performed by computers or machines or software. PSE provides integrated human friendly innovative computational services and facilities for easy incorporation of novel solution methods to solve a target class of problems. PSE is an innovative concept to enrich our e-Science, e-Life, e-Engineering, e-Production, e-Commerce, e-Home, etc. The PSE-relating studies were started in 1970's to provide a higher-level programming language than Fortran, etc. in scientific computations. The trend at that time was natural to deliver more human-friendly programming environment, and was resulting in PSE, CAE (Computer Assisted Engineering), libraries, etc. At present PSE covers a rather wide area, for example, program generation support PSEs, education support PSEs, CAE software learning support PSEs, Grid/Cloud computing support PSEs, job execution support PSEs, e-Learning support PSEs, etc. This review paper includes the PSE definition, a brief history of PSE, example PSE study activities, uncertainty management PSE and a future research directions in PSE.

1 INTRODUCTION

Problem Solving Environment (PSE) concept provides integrated human-friendly innovative computational services and facilities for easy incorporation of novel solution methods to solve a target class of problems. For example, a PSE generates a computer program automatically to solve differential equations[1-12]. Now the PSE concept covers rather wide areas in our society. PSE is an innovative concept to enrich science, human life, engineering, production and our society toward a programming-free environment in computing science. In the PSE concept, human concentrates on his/her target problems and works on solutions, and a part of application of solution, which can be solved mechanically, is performed by computers or machines or software. At present many kinds of computer-assisted problem solving environments are found everywhere in our life and in our society.

On the other hand, even today human power still contributes greatly to develop and write new softwares. For example, in scientific researches scientific discoveries are supported by theory, experiments and computer simulations. New researches tend to require new computer programs to simulate phenomena concerned. In another example, in developing new products engineers would also need new computer programs to develop the products cost-effectively. They may have to develop the new programs or learn how to use the programs for the product development. New services may also need new software systems. Therefore, the researchers and engineers may write or develop the new computer programs or learn how to use the programs. They do not like to develop nor learn the computer programs to solve their problems, but they like to devote their efforts to solve their target problems themselves.

In addition, computer simulations became the third important method after theoretical and experimental methods in science and engineering. Computer assisted problem solving is one of key methods to promote innovations in science and engineering, and contributes to enrich our society and our life from scientific and engineering sides.

The PSEs have provided the new directions to support users, engineers and scientists for

developing new services and new softwares, and also for solving their target problems based on computer systems.

The PSE-relating studies were started in 1970's to provide a higher-level programming language than Fortran, COBOL, ALGOL, PL/I and others in scientific computations. The trend at the time was reasonable to deliver more human-friendly programming environment beyond the higher-level languages shown above. Then the PSE research activity was started as well as activities of Computer Assisted Engineering (CAE) and software libraries. After the intensive developments in computer hardware and also in computer algorithms, researchers and engineers had expected an innovation in program writing and developing power. However, the enhancement in the programming power was relatively slow and weak compared with the enormous evolutions in the present hardware and algorithm power enhancements.

At present PSE covers a rather wide area, for example, program generation support PSE, education support PSE, CAE software learning support PSE, grid/cloud computing support PSE, job execution support PSE, learning support PSE, uncertainty management in scientific computing, PSE for PSE generation support (PSE for PSE), etc.

The paper includes a brief history of PSE, example PSE study activities and a future of PSE, including uncertainty management in scientific computing.

2 COMPUTER-ASSISTED PROBLEM SOLVING ENVIRONMENT (PSE)

PSE is defined as follows: "A system that provides all the computational facilities necessary to solve a target class of problems. It uses the language of the target class and users need not have specialized knowledge of the underlying hardware or software"[6]. PSE provides integrated human-friendly innovative computational services and facilities to enrich science, life, engineering, production, commerce and our society. Based on the PSEs, human concentrates on target problems themselves, and a part of solution is performed mechanically by computers or machines or software.

In computing sciences, we need the computer power, the excellent algorithms and the programming power in order to solve scientific problems leading to scientific discoveries and development of innovative new products and services. So far, the computer power and the computing algorithms have been developed incredibly, and have provided enormous contributions to sciences, productions and services. On the other hand, the programming power has not been developed well. The concept of PSE was proposed to support the programming power in science and engineering, and has been explored for decades.

In 1985, IFIP (International Federation for Information Processing) WG2.5 (Numerical Software)[16] organized a working conference on PSE and published the proceedings[17]. In 1991, a working conference on Programming Environments for High-Level Scientific Problem Solving was held[18]. In addition, a book on PSE was also published[19]. In 2007, a working conference on Grid-Based Problem Solving Environments was held[20]. A working conference on Uncertainty Quantification in Scientific Computing was held in 2012[21]. The PSE activity including scientific computing environments is one of research projects in IFIP WG2.5[16]. In these decades, international conferences tend to include the topic of PSE as one of standard topics in scientific computing. It has been recognized that PSE is an important research area in scientific computation and high-performance computing. In parallel, the PSE activities have started in several societies, scientific groups and countries. For example, in Japan, the PSE research group started in 1998 based on the previous individual PSE study activities, and the Japan Society for Computational Engineering and Science (JSCES) started in 1995, including the Study Group on PSE[22, 23].

The PSE studies have been extensively explored over the past few decades. The explorations have been supported by the reinforced computer power and algorithm power. PSE has boosted the programming power, and have enriched problem solving methods in science and engineering to bring us innovations.

One of PSE studies[1-12] has been extensively explored in order to support engineers and

scientists to compute or solve their own problems based on for partial differential equations (PDEs), for example. One of the major objectives in PSE researches is to help users compute or solve their problems without heavy tasks, for example, without complete knowledge for computations[24] and/or the programs used. In this sense, the PSE provides an infrastructure for software for computational engineering and sciences.

One of typical PSEs for PDEs-based problems is ELLPACK[8, 24]. ELLPACK is a high level system for solving elliptic boundary value problems. One can solve routine problems by simply writing them down and naming the methods to be used. The ELLPACK high-level language can reduce the programming effort for a "routine" elliptic problem.

Another typical PSE for PDEs-based problems is DEQSOL[7, 10, 11]. DEQSOL was designed to develop an easy-to-use system for problem solving of PDE-based problems by finite difference method and finite element method. DEQSOL creates optimal Fortran codes oriented to the Hitachi vector processors.

Another PSE system of NCAS[1, 2, 4, 9] inputs a problem information including PDEs, initial and boundary conditions, and discretization and computation schemes, and outputs a program flow graph, a C-language source code for the problem and also a document for the program and for the problem (see Fig. 1). On a host computer a user inputs his/her problem, and NCAS guides the user to solve the problem. The distributed PSE for PDEs consists of several modules: problem description, discretization, equation manipulation, program design, program generation, documentation support, module liaison and job execution service. Each module is distributed on distributed computers. Each distributed module communicates with the host module, so that outputs from each module are visualized. Independent modules, which are developed by other engineers or users for one of the functions specified above can also be used after adjustments to the distributed PSE interface[25], if necessary. The module liaison module generates an adapter module for the distributed PSE modules. The adapter module generated by the module liaison system inputs output data from preceding modules and/or external modules, and connects the data to the input data for the next module. The PSE contains all the information of the problem, PDEs, discretization scheme, mesh information, equation manipulation results, program design structure, variables and constant definitions and program itself. Therefore, the documentation support module also generates a document for the program generated together with the problem itself in the PSE[26].

A PSE module in NCAS also helps users generate MPI-based parallel simulation programs based on PDEs[4]. The NCAS capability explores possibilities to visualize and steer the parallel program design process. At present NCAS supports a domain decomposition in a design of a parallel numerical simulation program, and the domain decomposition is designed or steered by users through a visualization window. After designing the domain decomposition, the parallel program itself is also designed and generated in NCAS, and the designed parallel program is visualized and steered by a Problem Analysis Diagram (PAD). In NCAS, MPI functions[27] are employed for message passing, and a single program multiple data (SPMD] model is

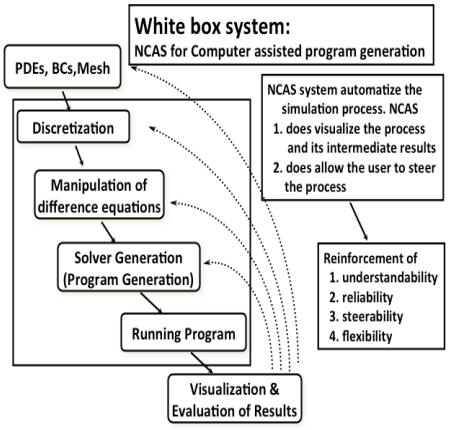

Fig. 1 An example PSE for computer assisted scientific program generation support: NCAS. NCAS inputs partial differential equations (PDEs), initial and boundary conditions, discretization method and algorithm, and outputs a C language program. The PDEs are automatically discretized and the program is generated mechanically. NCAS is a white box system, in which users can see and steer all the processes of program generation. NCAS system contains all the information for program generation, including basic equations, discretization schemes, discretized equations, boundary and initial conditions, mesh structure, program structure, and definitions of variables and constants. Therefore, a document for the corresponding program is also generated together with the program itself.

supported. The visualization and steering capabilities provide users a flexible design possibility of parallel programming.

Some PSEs provide a job execution support service on cloud or grid[28, 29]. It is difficult for users to submit jobs to distributed computers and to retrieve calculation data from them in scientific computing. A robust job execution service system was also developed in a closed distributed computer system[28]. The job execution service system consists of dynamic system management servers, execution servers and data servers. The dynamic system management server is duplicated in order to keep the system robust, and has an assistant management server. The dynamic system management server has a function of the job execution system management, including software deployment, program compilation, job execution, job status retrieval and computing data retrieval. This system does not require special middleware such as Globus[30] or UNICORE[31] or so. Users access the WWW page on the dynamic system management server, and the clients submit jobs. After the submitted job finishes, the dynamic system management server collects the information from other distributed computers. The dynamic management server and its assistant server move dynamically to new servers, if the present servers become busy. The dynamic system management server also demands the execution server to transfer the result data to the optimal data server. The dynamic system management server copies the computing data and sends the compressed computing data to another optimal data server in order for a robust data storage system. The clients can deploy their programs, execute jobs and retrieve the result data by accessing only the WWW page in the job execution service system. This job execution management server also has a function of automatic system construction, so that the users can manage the setup of the job execution management system easily on their closed distributed computers.

Another remarkable example of PSE is an education support PSE[32]. Network-based learning has been taking an important role in education as helpful education tools. However, it is difficult for teachers to retrieve education data from students or to obtain data from the student activities. Therefore, a problem solving environment (PSE) for the education and learning support: TSUNA-TASTE[32] was developed. The TSUNA-TASTE system collects the system-usage statistics, the information for the windows used and the operation situation of the mouse and key board of all students. The data, which the system TSUNA-TASTE collects, are stored in a database on the TSUNA-TASTE system server. Based on the data collected, teachers can have the learning status data for each student, and can guide the students in a better way.

Another research issue in PSE is validation, verification and uncertainty control in scientific simulations. When a software gives incorrect results for users, it may cause some difficulties, errors and accidents, depending on target problems[21, 33-37]. The validation and verification mechanism is essentially important in scientific computing. This point was also pointed out by E. Houstis, J. Rice and his colleagues[38]. Standardization and benchmark problems in each field may help to perform the validation and verification. In addition, uncertainty management must be addressed intensively in order to avoid serious accidents and disasters in our society. PSE is one of candidates to manage the uncertainty in a relatively easy way[39]. The topic on the uncertainty is also discussed in this paper. There are many PSE examples studied so far. In the references of [17-20] and [25] one can also find the example PSEs. In the next section typical example PSEs are introduced.

3 PSE EXAMPLES

3.1 A program generation support PSE

PSE studies [2-14] for partial differential equation (PDE) based problems have been extensively explored in order to support engineers and scientists to compute or simulate their problems and products on computers in e-Sciences and e-Productions. One of the major objectives in PSE researches is to help users compute or simulate their problems without heavy tasks, for example, without complete knowledge [11, 12] for computations or without a full programming [2-13].

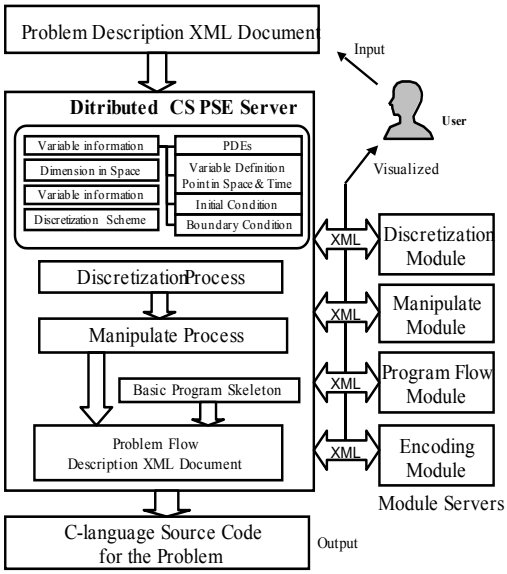

Fig. 2 Distributed-PSE: NCAS workflow.

In this subsection a program generation support PSE, called NCAS is presented. NCAS inputs partial differential equations (PDEs), the initial and boundary conditions, the discretization method and the algorithm, and outputs a C language program for the problem. The PDEs are automatically discretized and the program is generated mechanically. NCAS is a white box system, in which users can see and steer all the processes of the program generation. NCAS contains all the information for program generation, including the basic equations, the discretization schemes, the discretized equations, the boundaries and the initial conditions, the mesh structure, the program structure, and the definitions of all the variables and the constants. Therefore, a document for the corresponding program is also generated together with the program itself. In PSE for PDEs problems, one of problems, which should be addressed, is to develop huge PSE systems, including reusability of legacy PSE software. In order to solve this problem, a module-based PSE is proposed[9, 40]; each PSE module solves a part of PSE tasks, for example, a problem description interface, a discretization module, a scheme suggestion module, a program flow designer, a program generator, a data analyzer, a visualizer, and so on. If each module can be developed independently and works cooperatively and smoothly to solve one PSE job, the heavy work of PSE development may be drastically relaxed. In this subsection a distributed PSE, called NCAS, is introduced, which supports users to generate computer programs[1-4, 9, 26, 40].

The PSE system of NCAS inputs a problem information including discretization and computation schemes, and outputs a program flow graph, a C language source code for the problem and also a document for the program and for the problem. On a host computer a user inputs his/her problem, and the host guides the user to solve the problem. The distributed PSE for PDEs consists of several modules: a problem description, a discretization, an equation manipulation, a program design, a program generation, documentation support, a module liaison and a job execution service. Each module is distributed on distributed computers, and all the information is described by the Extensible Markup Language (XML) including the Mathematical Markup Language (MathML). Each distributed module communicates with the host module by using XML documents, so that outputs from each module are visualized. Independent modules, which are developed by other engineers or users for one of the

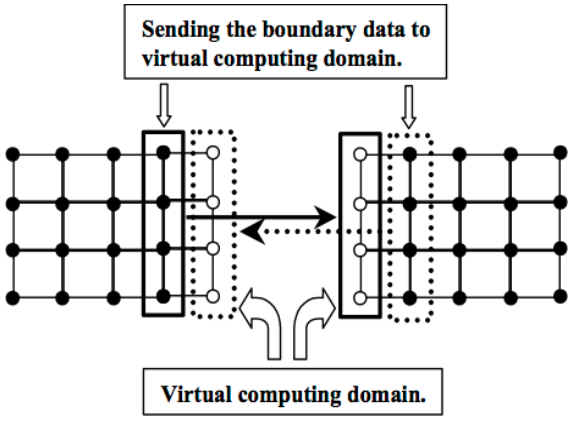

Fig. 3 Boundary data are communicated by the MPI functions in NCAS among domains decomposed. The MPI functions are automatically inserted into the program designed and generated in NCAS. The Finite Difference method (FDM) is employed in this example.

functions specified above can be also used after adjustments to the distributed PSE interface, if necessary. Therefore, the concept of the distributed PSE extends the potential of conventional PSE systems. The PSE contains all the information of the problem, PDEs, discretization scheme, mesh information, equation manipulation results, program design structure, variables and constant definitions and program itself. Therefore, the documentation support module also generates a document for the program generated and the problem itself in the PSE. The module liaison module generates an adapter module for the distributed PSE modules. The adapter module generated by the module liaison system inputs output data from preceding modules and/or external modules, and connects the data to the input data for the next module. The program generation PSE module provides a workflow shown in Fig. 2, and the user follows the workflow navigation for a problem generation.

The NCAS modules also help users generate MPI based parallel simulation programs based on partial differential equations (PDEs). The NCAS capability explores possibilities to visualize and steer the parallel program design process. At present NCAS supports a domain decomposition in a design of a parallel numerical simulation program, and the domain decomposition is designed or steered by users through a visualization window. After designing the domain decomposition, the parallel program itself is also designed and generated in NCAS, and the designed parallel program is visualized and steered by a PAD diagram. In NCAS, MPI functions are employed for message passing, and a SPMD (single program multiple data) model is supported. The visualization and steering capabilities provide users a flexible design possibility of parallel programming.

In the parallel program generation support in NCAS, for the data communication among the processors, the MPI functions are used. At least the boundary data for each domain decomposed are required to complete the computation in the adjacent processor (see Fig. 3). In NCAS the MPI functions are also automatically inserted to complete the parallel data communication programming. After specifying the domain decomposition information in NCAS, the parallel program is generated and provided to the users.

Figure 4 presents an example description of an input problem information, and Fig. 5 shows an example domain decomposition information. Through the NCAS visualization windows, for examples, shown in Figs. 4 and 5, one can check all the information and can also edit the information. In NCAS, after setting all the information for the problem description, the dicretization information

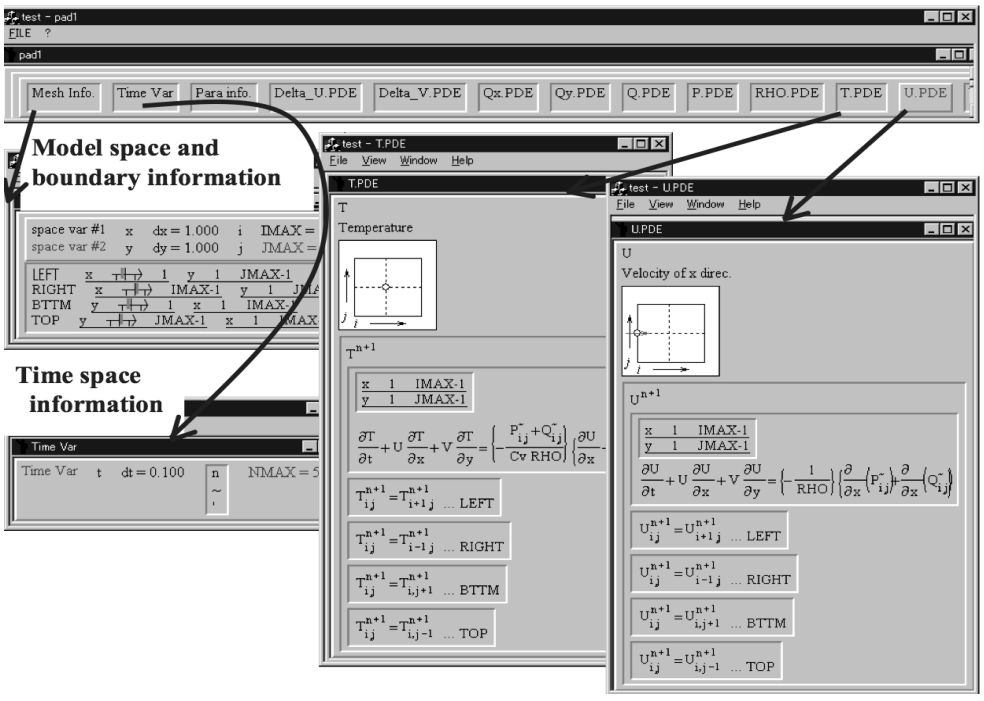

Fig. 4 An example PDE-problem description in NCAS. On each window users can edit the input description.

and the parallelization information through the NCAS windows, all the information is visualized to the users and the users can edit all the information through the windows. The discretization of each PDE is also performed automatically; depending on the discretization information which users input through the NCAS windows, the PDEs are discretized and manipulated appropriately according to the PDEs solving scheme. Then NCAS designs the parallel program for the problem, and outputs the parallel program and the corresponding document. Figure 6 shows an example MPI program automatically generated in NCAS.

In order to check the dynamic load balance function automatically generated by NCAS, during the computation an additional load was applied as shown in Fig. 7 (the left graph): by the additional load the computation time increases much in this specific case, if the static load balancing is used. When the dynamic load balancing method is selected in this example case, NCAS generates the functions, which measure the load balance of each machine dynamically, and according to the measured result each domain size is changed and adjusted dynamically to minimize the computation time. The right graph in Fig. 7 demonstrates the viability of the dynamic load balancing functions generated in NCAS, and the computation time reduction is significant in this case.

In the distributed PSE all the modules are distributed on network-linked computers. The information for the distributed modules and the computers are registered in a host computer. Newly developed modules by some users or scientists or so can be also registered in the host PSE server. The distributed PSE host server has the registered information for the modules oriented to one specific purpose, and users can obtain the information for each module and can select one of the modules to perform one task in all the PSE process.

The communication is accomplished through an interface using WWW server and Applet. The PSE server sends information described by XML to a module, and the module performs the task. The module sends the result based on the input XML information back to the PSE server. The result is visualized so that the user can check if the result is appropriate. After the successive processes, finally the NCAS generates a designed program flow and then a C program.

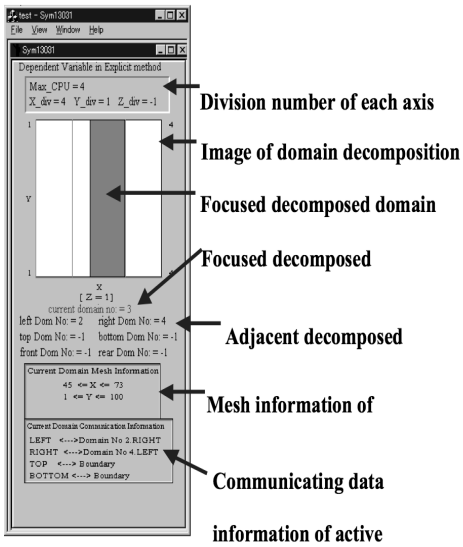

Fig. 5 Input and visualization of domain decomposition information.

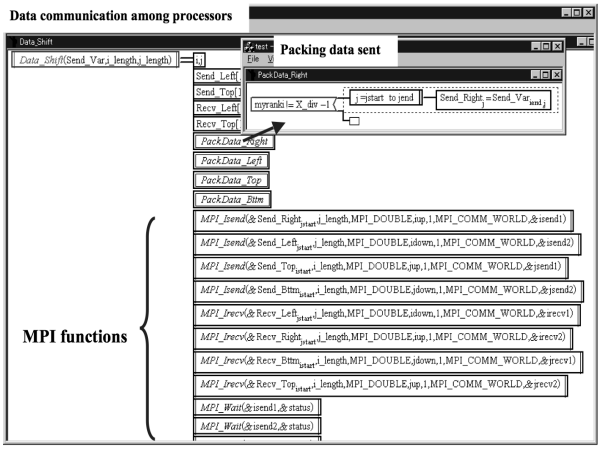

Fig. 6 Visualization of MPI functions designed for a domain decomposition information in NCAS.

3.2 An education support PSE

Network-based e-Learning is one of important education ways. In addition, the network-connected personal computers have become popular to schools and homes widely. In the network-based e-Learning, each learner can access education contents through the network anytime and anywhere. In an actual education, a network-based e-Learning system becomes popular in a long-distant learning and at the same time in a class-room education. Even inside class rooms, each computer is connected and can be used as a detecting device for the learners' progress and status. An e-Learning server may have facilities such as a user identification method or a file sharing tool in the network-based environment.

It would be difficult for teachers to know the learning state of students through each personal computer connected by a network. Without the detailed information of the students' achievement, it is difficult for the teachers to perform an appropriate guidance and education depending on the students' learning level. Therefore, the state of the students is important and required for the suitable guidance. The education-support PSE system, which provides teachers the student-achievement information, helps them in their teaching planning or the appropriate guidance.

The PSE concept was proposed to support the programming activity and also to provide integrated human-friendly computational facilities in e-Sciences and e-Productions[1-19]. In this subsection, an education and learning support PSE system: TSUNA-TASTE is introduced[32].

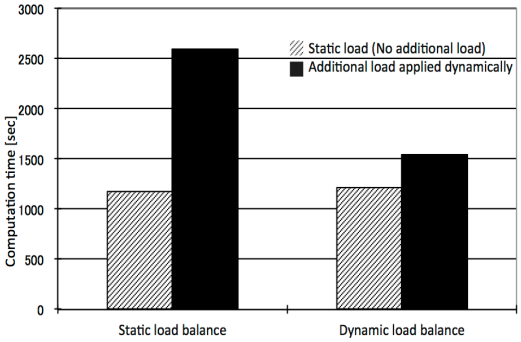

Fig. 7 A performance test result for a dynamic load balance. An additional load was applied during the computation, so that the computation time increases as shown in the left graph. When the dynamic load balancing function generated automatically by NCAS is used to this specific case, the domain size changes automatically depending on the machine load during the computation, and the result of the dynamic load balancing in the right graph shows the viability of

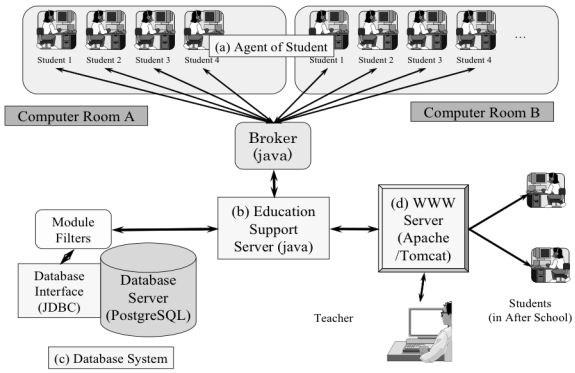

Fig. 8 Outline of the Computer assisted education support PSE: TSUNA-TASTE system.

The network education support system (TSUNA - TASTE) consists of four parts (see Fig. 8). The first part is an agent of student (Fig. 8(a)). It is a software, which always works on each personal computer of the student. The agent obtains the operation information of each student. The data are obtained from the operation information of the student through the OS with a resident software working on the personal computer of each student. The second part (Fig. 8(b)) is the education support server, that collects the data, which each student agent obtains via the network. The third part (Fig. 8(c)) is the database system. The database system stores the student profile data, the student personal data, the curriculum data and the teacher's personal data. The fourth part (Fig. 8(d)) is the WWW server displaying the information stored in the database. The WWW server (Servlet system) provides an interface to the TSUNA-TASTE handling.

The agent for each student resides on the memory of the personal computer of the student and performs the following three operations. Firstly the agent exchanges the messages with the education support server. The education support server transmits the messages to each agent. The student agent analyzes the messages, and obtains the process priority and the start time of the process described in the messages. The agent stores the message data in its task table. Secondly the agent

manages the module program execution based on the task table. The module programs are small-size programs, which retrieve and output the student personal data from the student computers. The student personal data includes the achievement data, the operation data, the active window names and the process names. The third operation is a job to send back the data, which each module program collects, to the education support server. The module programs obtain the information of the student personal data from the OS of the student PCs. The module programs are implemented in the C++ language.

The module collects information about the student, however it does not store the raw data for security. It converts the raw data into statistics data. The transmission data are encoded and transferred. Furthermore, the personal information is not included in the data transmitted to the server. Thus, this system is robust for the electronic eavesdropping of data.

The education support server receives the operation data of the students through the student agent, and transmits the teacher's instructions to the students through the student agent. The education support server marks the students' absence, and identifies the students and their PCs. The education support server sends the messages of the data process demand to the agent of the student, and transmits the student personal data to the database server. The education support server also retrieves the student personal data requested by the teachers through the WWW server, and sends them back to the WWW server (see Fig. 8(d)) in the TSUNA-TASTE. The education support server is built using the Java language.

The data, which the education support server receives, are stored in the database. The database includes the private information of each student and teacher. The data contains the private information such as college student registration numbers, mail addresses and so on. These unchanged data are stored in the database together with the temporal data like the site of the student PCs. The server can receive the data from about 120 personal computers at the same time.

The WWW server system provides the user interface of the TSUNA-TASTE system. The teachers can obtain the state data of the students from the WWW system. The WWW server system presents the student achievement data, the learning progress and error occurrences situation during the programming exercises. The WWW system also provides an input interface to control the action of the TSUNA-TASTE: Through the WWW system, teachers can send a data gathering command, monitor the students' present usage of applications, and kill the unnecessary application processes on the students' PCs. The TSUNA-TASTE may open a new helpful e-Learning world.

3.3 Job execution support PSE on GRID

It is difficult for users to submit jobs to distributed computers on Cloud /Grid and to retrieve calculation data from them in scientific computing. In this subsection, a robust job execution service system is introduced in a closed distributed computer system[28, 29, 41]. The job execution service system consists of a dynamic system management servers, execution servers and data servers as shown in Fig. 9. The dynamic system management server is duplicated in order to keep the system robust, and has an assistant management server. The dynamic system management server has a function of the job execution system management, including software deployment, program compilation, job execution, job status retrieval and computing data retrieval. This system does not require special middleware for Cloud /Grid. Users access the WWW page on the dynamic system management server, and the clients submit jobs.

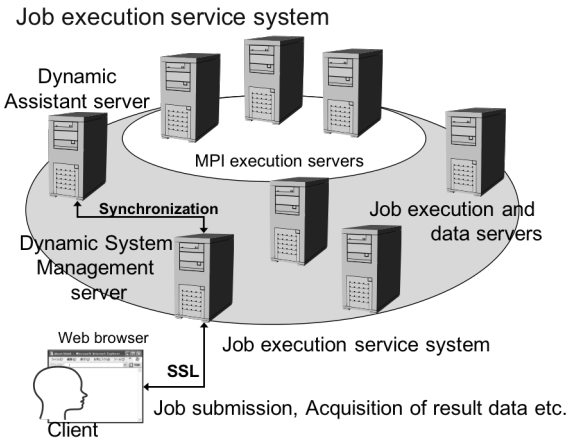

Fig. 9 Job execution service on distributed computers n Cloud / Grid.

After the submitted job finishes, the dynamic system management server collects the information from other distributed computers. When the present servers become busy, the dynamic management server and its assistant server move dynamically to new servers. The dynamic system management server also demands the execution server to transfer the result data to the optimal data server. The dynamic system management server copies the computing data and sends the compressed computing data to another optimal data server in order for a robust data storage system. The clients can deploy their programs, execute jobs and retrieve the result data by accessing only the WWW page in the job execution service system. This job execution management server also has a function of automatic system construction, so that the users can manage the setup of the job execution management system easily on their closed distributed computers.

Users access the WWW page on the dynamic system management server, and the clients submit jobs. After the submitted job finishes, the dynamic system management server collects the information from other distributed computers on Cloud / Grid. The clients can deploy their programs, execute jobs and retrieve the result data by accessing only the WWW page in the dynamic system management server.

The job execution service system acquires necessary resource information for servers for job execution and for data retrieval and storage. The resource information contains CPU architecture name, CPU operation frequency, total memory, memory in use, unused memory, load average and unused capacity of hard disk. The system sorts the resources in order for effective job execution. The users can find the resource information on the job execution service system WWW page.

Clients access the dynamic system management server through the WWW page of the system, and perform computing. Through the WWW page, the clients can up-load source files or executables to the dynamic system management server, select computing servers from among resources recommended by the system, and set execution environment. When two or more files are required for one job, the client should compress those files. When MPI jobs are executed, computing servers, on which MPI is installed, are recommended to the clients.

The compilation command, the execution method, the comment and the server name for job execution are specified by clients. The clients can also specify the storage location of the result data of the job. When the clients do not especially specify the storage data server, the system forwards the result data to the best data server. When input information is not sufficient, the job execution service system displays an error message, and advises to input the required input data. The clients can select the execution methods, or make scripts for the execution on the WWW page in a compressed file format.

When the job setting ends, the job execution service system forwards the job to a pertinent server or a server set based on the setting information. The setting file is described in XML, and contains the computing server information, the compilation command, the execution information and the data storage server information. When a compressed file, which contains source files/binaries and a make file, is sent to the computing servers, the compressed file is decompressed and the decompressed information is sent to the dynamic system management server, so that the clients can check if the file decompression is succeeded. When the compilation or the execution errors appear, the computing server notifies them to the dynamic management server. When the execution server specified is occupied by another job, the job is scheduled by the dynamic system management server.

When a job ends, the job execution server forwards the result data to a pertinent server based on the setting information. In addition, its compressed result data is stored in another data server. The result data duplication makes the data server robust and fault tolerant. When no data server is specified in the setting information, the computing server asks the dynamic system management server about the data storage servers. Based on the unused hard disk capacity, the better two data storage servers are selected from among the servers, on which no jobs run. One is for the result data uncompressed and the other is for the compressed backup data. When the result data is stored on the data servers specified, the data server locations are notified to the dynamic system management server. The client can refer to and can download the data from the WWW page on the dynamic

system management server.

4 CONCLUSIONS

The PSE has been extensively explored over the past few decades. The explorations have been supported by the reinforced computer power and algorithm power. PSE will boost up the programming power, and will enrich our e-Life and e-Science. In the near future of the PSE development we should consider how to create a PSE. To build up a PSE is a very hard task and needs huge human efforts. Therefore, PSE researchers have still been meeting this difficulty. In this research issue meta PSE or PSE for PSE may play an important role to build up service-oriented PSEs. One example of the meta PSE is a PSE Park[39], in which many modules, developed by PSE researchers / developers, are distributed. Each module has one function or may be a one PSE, and is developed by many independent researchers and developers. By connecting the modules, PSE researchers or users can construct a single-purpose PSE or so. The interface should be opened, so that each PSE connector can be easily developed by each user or researcher or developer. The module mediator / connector may come into play there. The module base PSE may open a new PSE World.

Another research issue in PSE is validation, validity and uncertainty. When a PSE gives a wrong result for users, it may cause some difficulties, errors and accidents, depending on target problems. The validation and verification mechanisms are essentially important as usual software.

ACKNOWLEDGEMENTS

This work was supported partly by JSPS, MEXT and Japan Society of Computational Engineering and Science. The authors would like to extend their appreciations to Prof. J. Rice, Prof. E. Houstis, friends in IFIP WG2.5, and friends in the PSE research group in Japan including Prof. S. Hioki, Dr. Y. Miyahara, Prof. D. S. Han, Dr. S. W. Hwang, Prof. T. Teramoto, Dr. H. Usami, Dr. T. Maeda, Dr. Y. Manabe, Dr. H. Kobashi, Dr. Y. Hayase and our former students and friends contributed to the works relating to the paper.

A Computational Fluid Dynamic Investigation of the Obesity-altered Hemodynamics in Children and Adolescents

Asimina Kazakidi*

*University of Strathclyde

ABSTRACT

Childhood obesity has become one of the major challenges of our century, taking epidemic proportions. Obesity, mainly a dietary disease, is known to advance endothelial dysfunction [1], an early sign of atherosclerotic lesions underling most cardiovascular diseases. Endothelial damage in high-risk paediatric patients can be clinically assessed with measurements of the aortic and carotid intima-media thickness (IMT), and flow-mediated dilatation (FMD) of the brachial, radial, and femoral arteries [2]. However, it is not yet clear how the haemodynamic environment is altered in this particular group of patients and which flow-related mechanisms contribute to early vascular changes. This work will discuss a computational model of an arterial conduit with compliant walls during FDM that attempts to clarify some of these aspects. Solutions to the time-dependent, incompressible Navier-Stokes equations are based on high-fidelity finite volume and hybrid Cartesian/immersed-boundary (HCIB) methods [3] that overcome several of the shortcomings of conventional computational fluid dynamic methods and provide increased spatial flow analysis. The codes have previously been validated and used extensively in various applications. Implementation of wall motion is particularly easy with HCIB methods, which are inherently capable of handling arbitrarily large body motions and allow for effective solutions of wall configuration. The model provides an evaluation of the haemodynamic shear stresses, a common indicator of early atherosclerotic lesion localisation. Future work will include multi-scale modelling that combines high-resolution 3D blood flow computations, with macroscopic and microscopic features of the vascular environment. Further haemodynamic metrics, such as the time-averaged wall shear stress (TAWSS), the oscillatory shear index (OSI), and the transverse WSS will also be assessed, in conjunction with patient data. Stress-Based Topology Optimization of Multi-Material Truss Lattice Structures

Hesaneh Kazemi*, Ashkan Vaziri**, Julián Norato***

*University of Connecticut, **Northeastern University, ***University of Connecticut

ABSTRACT

We present a framework for the stress-based topology optimization of truss lattice structures made of multiple materials for desired bulk properties. Each strut in the lattice can be made of one of several available materials. We aim to solve lattice design problems subject to stress constraints, such as maximizing the lattice bulk modulus subject to stress constraints under an applied far-field traction. We employ the geometry projection method to map the geometry of each strut smoothly onto a continuous density field over a fixed finite element grid for analysis. Following recent work by our group, we adapt strategies used in density-based topology optimization to the geometry projection framework. These strategies address known challenges in stress-based topology optimization, namely the onset of singular optima and the large number of constraints. These strategies include the definition of a suitable relaxed stress, the use of aggregation functions to condense elemental stress constraints into a single optimization constraint, and the use of adaptive constraint scaling to ensure the desired stress limit is tightly satisfied. To accommodate multiple materials, we employ a novel aggregation scheme to perform the union of struts made of different materials. A size variable per material is ascribed to each strut in the lattice. Subsequently, an effective density per material is defined at each point, and the effective properties at that point are thus a function of the properties of the multiple available materials. To define the weights that determine the contribution of each strut to the effective density of a material, we adapt the Discrete Material Optimization (DMO) method. A size variable of unity indicates that the strut is made of the corresponding material. Furthermore, all size variables can be zero for a strut, allowing the optimizer to remove the strut altogether from the lattice. To avoid intermediate size variables in the optimal design, we penalize the size variables so that they are either 0 or 1. As opposed to DMO method, which enforces the penalization directly through the weighting factors, we penalize the size variables via an inequality constraint in the optimization (a ‘discreteness constraint’). Moreover, each strut should be made of at most one material. Therefore, we impose another optimization constraint to ensure each strut has no more than one size variable of unity (a ‘mutual material exclusion’ constraint). We demonstrate the effectiveness of our method via several numerical examples.

ABSTRACT

The simulation of crack propagation in ductile materials using the finite element method requires appropriate models for describing the nucleation, growth and coalescence of voids in a robust way. Local models, such as Rousselier and Gurson-Tvergaard-Needleman are now available in the finite element softwares as Cast3m [3]. A large number of models of this kind can be found in the literature, but they suffer from numerical drawbacks. First, they often show a marked mesh dependency of the solution. Second, volumetric locking of the elements is common in elastoplastic damage models in near-incompressible conditions. These two major issues must be solved in order to insure the robustness of such approaches. Our goal is to propose a model which will be able to handle these two problems. The mesh dependency can solved by using regularization techniques, such as implicit gradient enrichment of an internal variable [1].The locking can be treated, either using selective integration techniques, or a mixed formulation [2], which adds the volume variation as a new variable in addition to the displacement. The proposed models, based on the existing Rousselier and GTN models in Cast3m [3], address both issues using an implicit-enriched gradient of damage, and include a mixed formulation in the local models to ensure the desired robustness. In this presentation, the new models and the implementation of the new models are first presented. In a second part, simulations of crack propagation using the proposed models for axisymmetric and compact-tensile specimens in 2D using the Cast3m finite element software [3] are used to illustrate the relevancy of the approach. Comparison of Immersed, Embedded, and Moving Domain Approaches for Coupled Air/Water/Granular Dynamics

Chris Kees*, Yong Yang**, Milad Rakhsha***, Leo Nouveau****, Guglielmo Scovazzi*****

*US Army ERDC-CHL, **US Army ERDC-CHL, ***University of Wisconsin, ****Duke University, *****Duke University

ABSTRACT

There is a compelling need for accurate, efficient, and robust computational models of granular media dynamics with tight coupling to multiphase air/water flow. Understanding riverine and coastal bank, dune, and sediment dynamics are just a few areas where fundamental science can be advanced with a computational laboratory representing, among other things, granular collisions and friction, air/water/solid surface tension forces, and high-Reynolds number incompressible flow. Having already invested heavily in development of conservative level set finite element methods for multiphase flow, a natural extension of our existing tools is the application of level-set-based approximations of the Nitsche approach to weak enforcement of fluid/solid Dirichlet boundary conditions [4]. The need to represent large-scale floating structures and vessels, however, also drove the development of boundary-fitted arbitrary Lagrangian-Eulerian formulations [1]. In this work we present an inter-comparison of several level-set approaches to the fluid-solid moving boundary, including the recently developed shifted boundary method [5], with a more traditional boundary-fitted deforming domain method [1]. We compare these methods in the context of modeling rigid particles interacting with air/water flow. These approaches, though recent, are not in principle new. Indeed, coupling the Discrete Element Method for granular materials to Finite Element Method has been addressed by many (e.g. [2,3]). The novel aspects of the current work are the coupling of air/water multiphase flow, higher-order FEM with immersed and embedded methods, and the opportunity for learning from inter-comparison of existing methods. ABSTRACT

We discuss aspects of the microscopic and the macroscopic stability of coupled, active elastomers with periodic microstructure based on a computational approach. The effective properties of the microstructured materials are determined via finite-element based computational homogenization of representative volume elements [1,2]. In the framework of the computational approach, localization-type macroscopic instabilities are detected by checking the strong ellipticity of homogenized moduli [3]. At the microscopic level, we determine bifurcation-type instabilities by means of a finite-element based Bloch-Floquet analysis [4]. The latter allows us to find altered periodicities of microstructures as well as critical macroscopic loading points [5]. Representative numerical examples will demonstrate the applicability of the proposed scheme to the detection of multiscale instabilities occurring in active elastomers. References: [1] K. Plastic Instability of Rate-Dependent Materials - Consideration of Isothermal and Adiabatic Conditions in Dynamic Tensile Tests -

Christian Keller*, Uwe Herbrich**

*Bundesanstalt für Materialforschung und –prüfung (BAM), Unter den Eichen 87, 12205 Berlin, Germany,
**Bundesanstalt für Materialforschung und –prüfung (BAM), Unter den Eichen 87, 12205 Berlin, Germany

ABSTRACT

During dynamic processes, a certain range of strain rates is often observed along loaded structures and components. For precise numerical simulations, it is necessary to determine rate-dependent properties in dynamic tests and to describe the material behavior correctly within an appropriate domain of strain rates including adiabatic heating effects at higher strain rates, typically higher than 10 s-1. In principle, numerical simulations are compared to experimental results to verify the applied material models. For dynamic tensile tests con-sidering ductile materials and large plastic deformation beyond uniform elongation, it is challenging to obtain comparable results due to plastic instability and necking of the spec-imen, e.g., [1]. Based on the strain gradient in a general tensile specimen, a theoretical criterion was de-rived describing the plastic instability in rate-dependent materials under isothermal condi-tions in [2]. It was applied to different multiplicative and additive constitutive relations and the analytical onset of necking was compared to results from numerical calculations of qua-si-static and dynamic tensile tests. The simulations of a sheet-metal specimen with rec-tangular cross-section were carried out using the Finite Element Method and it was found that the numerical calculated and the theoretical predicted onset of plastic instability agree very good. The analytical criterion for instability holds even for specimens without geomet-rical or material imperfections and confirms that the onset of plastic instability must be considered a material characteristic. However, real dynamic problems with higher strain rates are not isothermal, the heat gen-erated by plastic work is not dissipated to the surrounding and the temperature of the ma-terial increases significantly. Adiabatic heating and thermal softening must be considered within the constitutive relations of rate-dependent materials and the discussion of plastic instability. In this paper, an enhanced and more generalized approach for the description of the condition for stability is discussed and applied to phenomenological as well as more physical constitutive relations from the literature. This allows an individual assessment of the accuracy and verification of rate-dependent material models with respect to plastic in-stability. Towards Airframe Static Stress Requirements Improvement Using Probabilistic Analyses

Martin Kempeneers*

*AIRBUS France

ABSTRACT

The sizing by analysis approach is the most commonly used mean to demonstrate the structural integrity of an airframe component. Such an approach requires to account for the effect of all the physical parameters having a significant impact on the static strength of the part. These parameters can be for example: the mechanical loads, the material properties, the thermal environment, the built stresses… For static justification, the usual sizing by analysis approach used is of the deterministic type supported by probabilities. It means that it consists in considering a priori selected values for the parameters driving the static strength in order to assess the latter in a simple deterministic allowable vs applied load comparison check. The selection of the deterministic values is then based on probabilistic conditions. For the most important parameters (i.e. the mechanical load level and the material properties), the acceptable probability of occurrence to be considered are clearly specified in the certification regulations. Each of the other additional parameters to be taken into account in the analyses has also its own statistical distribution and an associated probability of occurrence. Most of the time, for these parameters, the selection of the deterministic values is based on engineering judgement and a low probability event (or even sometimes the worst case) is selected without further analysis (no detailed analysis of the effect of the parameters on the static strength). The reasons for doing so are most of the time for the sake of simplicity or because of a lack of method and/or data to do it better. This can result in the combination of very penalizing and unrealistic conditions in sizing analyses, and consequently taking into account scenarios beyond what needs to be reasonably considered. Rationalization can be done by using probabilistic assessments. This is the purpose of the present communication which defines a general approach to build probabilistic analyses intended to support the definition of improved static stress requirements reducing the accumulated conservatism.

Time Discretization Bi-Fidelity Modeling

Vahid Keshavarzzadeh*, Mike Kirby**, Akil Narayan***

*University of Utah, **University of Utah, ***University of Utah

ABSTRACT

For many practical simulation scenarios, modification of the time-step (large versus small) provides a simple low versus high fidelity scenario in terms of accuracy versus computational cost. Multifidelity approaches attempt to construct a bi-fidelity model having an accuracy comparable with the high-fidelity model and computational cost comparable with the low-fidelity model. In this talk, we present a bi-fidelity framework defined by the time discretization parameter that relies on the low-rank structure of the map between model parameters/uncertain inputs and the solution of interest. We show how this framework behaves on canonical examples, and we show real-world (practical) extensions of our methodology to molecular dynamics simulations.

Topology Optimization under Uncertainty with Multi-Resolution Finite Element Models

Vahid Keshavarzzadeh*, Robert Kirby**, Akil Narayan***

*University of Utah, **University of Utah, ***University of Utah

ABSTRACT

Abstract We present a computational framework for parametric topology optimization with multi-resolution finite element (FE) models. We use our framework in a bi-fidelity setting where a coarse and a fine mesh corresponding to low- and high-resolution models are available [1]. The inexpensive low-resolution model is used to explore the parameter space and approximate the parameterized high-resolution model and its sensitivity where parameters are considered in both structural load and stiffness. Our analysis provides computable error estimates for the bi-fidelity FE approximation and its sensitivity at each design iterate. We demonstrate our approach on benchmark density-based compliance minimization problems where we show significant reduction in computational cost i.e. the number of fine-resolution simulations for expensive problems such as topology optimization under manufacturing (geometric) variability while generating almost identical designs to those obtained with single resolution mesh [2]. To show the effectiveness of our bi-fidelity approach in estimating challenging quantities we compute the parametric Von-Mises stresses for the generated designs and compare them with standard Monte Carlo simulations. Computational Design of Nanocellulose Materials for Better Mechanical Performance

Sinan Keten*

*Northwestern University

ABSTRACT

Natural and engineered structural (load-bearing) nanocomposites often try to exploit microstructural configurations that lead to achieve remarkable mechanical properties such as damage tolerance. However, the mechanical properties of these materials depend strongly on both the chemistry of the interfaces and the microstructure of the material system, which complicates their design. In this talk, a new computational materials-by-design approach based on coarse-grained molecular simulations for understanding physical phenomena occurring at such disparate scales will be presented. I will discuss several cases where the coupling between nanostructure and chemical structure will lead to intriguing features, specifically focusing on nanocellulose neat films and nanocomposites. Drawing an analogy between thin films and nanocomposites, I will illustrate how understanding thin film simulations help us design better load-bearing nanocomposites with nanocellulose fillers. I will conclude with an outlook on impact tolerant polymer nanocomposites and tough interfaces inspired from biological systems.

A Novel Combination of Isogeometric Analaysis with Far-field Expansion Absorbing Boundary Conditions for Exterior Acoustic Problems

Tahsin Khajah*, Vianey Villamizar**

*University of Texas at Tyler, **Brigham Young University

ABSTRACT

We have devised a new method combining Isogeometric Finite Element Method (IGA-FEM) with Far-field Expansion Absorbing Boundary Conditions (FEABC) for time-harmonic exterior acoustic problems. The FEABC has been recently developed [1]. It constitutes an arbitrary accurate representation of the outgoing waves on a conveniently chosen artificial boundary. First, we derive a weak formulation of the corresponding boundary value problem that includes the FEABC in the FEM context. The construction of the FEABC is based on truncated series of the well-known Wilcox and Karp farfield expansions which are used for an exact representation of the outgoing waves in the exterior. As a result, the error of the combined method IGA with FEABC can be made as small as the error made in the interior of the computational domain by increasing the number of terms in the Karp's and Wilcox's expansions. Hence, it is possible to obtain extremely accurate numerical solutions with rather low discretization densities. Both the pollution and truncation errors are well controlled even for high frequency regimes. In fact, the accuracy of the solution on the artificial boundary and the farfield is limited by the computational resources. We will present some numerical experiments for moderate and high frequencies to show the effectiveness of our novel method. Computational Tools for Data-driven Design of Soft Robots

Mohammad Khalid Jawed*

*University of California, Los Angeles

ABSTRACT

We report a numerical simulation framework for the mechanics of soft robots comprised of slender structures, for application in data-driven structural design, material selection, and adaptive control. Owing to prohibitive computational cost, soft robots are often designed solely based on empirical laws through a tedious trial-and-error process with no quantitative guideline. Inspired by fast and efficient modeling of hair and clothes in the animation industry, we adapt algorithms for physically-based simulations from computer graphics. We extend the Discrete Elastic Rods method to develop a simulator for a wide class of robots comprised of multiple slender structures (rods or shells) with compliant joints. In parallel with computation, we perform experiments with biomimetic robots composed of soft thermal actuators and confirm the validity of the simulation tool. Given the large number of parameters and high degree of nonlinearity associated with the performance and functionality of soft robots, emergent machine learning techniques offer a promising avenue for their computational design and optimization. The robustness and speed of our simulation can enable data-driven analysis of a broad range of smart programmable structures beyond soft robots.

High Fidelity Anisotropic Adaptive Finite Element Method for Multiphase Flows with Phase Change

Mehdi Khalloufi*, Rudy Valette**, Elie Hachem***

*MINES ParisTech, PSL - Research University - Computing and Fluids Research Group, **MINES ParisTech, PSL - Research University - Computing and Fluids Research Group, ***MINES ParisTech, PSL - Research University - Computing and Fluids Research Group

ABSTRACT

We propose in this work a novel numerical framework, which allows dealing with the cooling of an immersed 3D solid surrounded by turbulent boiling flows with evaporation at the liquid-gas interfaces. Indeed, while standard numerical methods may not able to deal with these heat transfer interactions simultaneously: gas-liquid-solid interfaces, vapor formations and dynamics, and 3D cooling of a heated solid, therefore, we propose in this paper a novel Eulerian method to achieve this challenging task. The key-points to achieve these difficult simulations are the development of an adaptive Eulerian framework. It uses a Level Set method to separate each states and to track each phases. A Variational Multiscale solver for the Navier-Stokes equations, which can deal with turbulent multiphase flows, is extended with implicit treatment of the surface tension. The phase change is performed using the balance of heat fluxes at the interface without the use of conforming mesh. Instead, the use of an a posteriori error estimate leading to highly stretched anisotropic elements at the interface enables to drastically reduce the interface thickness. This avoids the need of interface reconstruction or interpolation procedure. Finally, in the numerical results section, a series of 2-D and 3-D problems are solved to verify the efficiency and accuracy of the proposed framework. The cooling of an immersed solid is also presented and shows good agreement with the experimental results.

Determining the Parameters of Constitutive Laws of XFEM and CZM for Modeling Premature Failures in Plated RC Beams

Mohammad Arsalan Khan*

*Dept. of Civil Engineering, Z.H. College of Engineering and Technology, Aligarh Muslim University, Aligarh-202002, India

ABSTRACT

Structures are strengthened with FRP or steel plates through external retrofitting. This technique has been in practice mainly for two reasons: ease of implementation and minimal aesthetic change in the structural component. However, RC beams strengthened with this technique suffer from premature failure(s); that is, a beam failing in undesirable modes of failure which are unpredictable and against which the beam is not initially designed. One critical mode of such failure is peeling, leading to a catastrophic failure by ripping off of the covercrete along the rebars and thereby further leaving the rebars exposed. Peeling usually starts from the end of the plate and propagates further depending on wide range of geometrical and material parameters. Debonding, which may also start from plate-end, has a different failure mechanism to peeling and so the defining parameters. However, in literature, both types of failure have largely been put in one category as a failure from plate-end; and solutions to the existing problem are largely limited to the mode-II debonding behaviour. This may be attributed to the complex nature of material behaviour, combined with geometrical non-uniformities under mixed-mode loading. Current study shows the suitability of XFEM and Cohesive Zone Model (CZM) models to respectively predict peeling and debonding failures in plated RC beams subjected to 4-point loading condition. XFEM model is utilised along with Concrete Damaged Plasticity model (CDP). Beams have been selectively picked from literature to cover a wide range of material and geometrical variables and the ones that are failing in peeling or debonding. NA series of numerical simulations are performed for different combinations of bond parameters and verified against experimental data to identify parameters of traction-separation constitutive models, defining peeling and debonding, in terms of key material properties. Considering a level of non-uniformity of result patterns associated with this problem, multiple regression analysis is performed to reach desired relations of bond parameters. Suitability of different bond-slip curves are then evaluated for CZM, where bilinear law is found to be a closest match with experimental observations. Suitability of the bond parameters, thus arrived, is demonstrated against the experimental data consisting of strain distribution, plate-end displacement, number of cracks, and load and mode of failure.

Scale Transition from Discrete to Continuous Models for Drying of Capillary Porous Media

Abdolreza Kharaghani*, Xiang Lu**, Evangelos Tsotsas***

*Otto von Guericke University Magdeburg, **Otto von Guericke University Magdeburg, ***Otto von Guericke University Magdeburg

ABSTRACT

Drying of porous media is a central process in many environmental and engineering applications. The physical processes involved are two-phase flow in porous media as well as phase transition. Two main approaches have been used to derive mathematical models for the drying process: The first approach considers the partially saturated porous medium as a continuum and partial differential equations are used to describe the mass, momentum and energy balances of the fluid phases. The continuum-scale models obtained by this approach involve constitutive laws which require effective material properties, such as the permeability, diffusivity, and thermal conductivity which are often determined by laborious experiments. The second approach considers the material at the pore scale, where the void space is represented by a network of pores. Micro- or nanofluidics models used in each pore give rise to a large system of ordinary differential equations with degrees of freedom at each node of the pore network. The characteristic length scale of the pore network models is several orders of magnitude smaller than the practically relevant length scale. A straightforward upscaling of the micro-scale models by using large pore networks is computationally costly, but it can be used to assess the quality of any chosen continuum-scale model as well as to estimate the effective parameters. When reliable estimates for these parameters have been obtained as functions of the pore size distribution and other material properties, the computationally much cheaper continuum-scale model may be used in future simulations without the need for further micro-scale simulations or experimental measurements. In this work, we demonstrate this scale transition with a three-dimensional pore network model at the micro scale and with the one-dimensional moisture diffusion model at the continuum scale. This is a quasilinear parabolic partial differential equation for the moisture content in the porous medium, where the effective moisture diffusion coefficient depends on the moisture content. We estimate this effective parameter from the post-processing of the (isothermal) micro-scale simulation results for multiple realizations of the pore space geometry from a given probability distribution.

On Relaxed Energy Potentials in Magnetomechanics

Bjoern Kiefer*, Thorsten Bartel**

*TU Bergakademie Freiberg, Institute of Mechanics and Fluid Dynamics, **TU Dortmund, Institute of Mechanics

ABSTRACT

The prediction of the effective macroscopic behaviors of micro-heterogeneous materials by means of adequate homogenization concepts is a classical problem in solid mechanics. Such analysis relies on the knowledge of geometrical, distributional and constitutive properties of the involved phases. It is well-known that standard homogenization schemes in micromechanics, such as the Taylor/Voigt and Reuss/Sachs assumptions, can also be interpreted as energetic bounds. Furthermore, energy relaxation concepts have been established that determine stable effective material responses based on appropriate convex, quasi-convex and rank-one convex energy hulls for multi-phase materials characterized by non-convex energy landscapes, see [2,3], and the references therein. In this contribution we propose analogous relaxation-based homogenization approaches for magnetizable solids---in extension of variational methods of magnetomechanics established in prior work, cf.~[1-3]. In parti\-cular, we introduce novel scalar and vector-valued magnetic potential perturbation schemes. These yield relaxed effective free energy/enthalpy densities which simultaneously satisfy magnetic induction and magnetic field strength compatibility requirements---i.e.~the magnetostatic Maxwell equations---at phase boundaries. It is shown that the relaxed vector potential scheme requires the additional setting of gauge conditions to avoid spurious solutions and thereby improve its convergence behavior. In this context, we also propose adequate choices of thermodynamic potentials and their implications on the theoretical framework for constitutive modeling as well as corresponding numerical treatments. Furthermore, the challenges of implementing homogenization schemes based on potentials that are simultaneously relaxed with respect to mechanical and magnetic degrees of freedom are discussed as part of on-going work. Finally, it must be emphasized that the established variational relaxation schemes are equally applicable to the modeling of multi-phase solids exhibiting electromechanical coupling. Isogeometric Phase-field Description of Brittle Fracture in Plates and Shells

Josef Kiendl*, Davide Proserpio**, Marreddy Ambati***, Laura De Lorenzis****

*Norwegian University of Science and Technology, **Norwegian University of Science and Technology, ***TU Braunschweig, ****TU Braunschweig

ABSTRACT

Phase-field modeling of brittle fracture is a modern promising approach that enables a unified description of complicated failure processes, including crack initiation, propagation, branching, and merging, as well as its efficient numerical treatment [1]. In this work, we apply the phase-field fracture approach to shell structures, describing both the structure and the phase field by surface models. For avoiding fracture in compression, we split of the deformation tensor in tension and compression terms as proposed in [1]. We show that this requires special attention in structural models like plates and shells, where bending deformation typically induces both tension and compression at opposite sides of the structure. We propose a new approach [2], which allows for a varying degradation through the thickness while the phase field is represented as a single two-dimensional field on the shell's middle surface. The numerical implementation is based on isogeometric analysis with a rotation-free Kirchhoff-Love shell formulation for structural analysis. We extended the NURBS-based implementation to locally refinable LR-NURBS enabling local and adaptive mesh refinement, which is a crucial aspect for computational efficiency considering that the phase-field approach requires very fine mesh resolution locally in the cracked areas.

A High-order Local Discontinuous Galerkin Scheme for Viscoelastic Oldroyd B Fluid Flow

Anne Kikker*, Florian Kummer**

*Graduate School CE, Technische Universität Darmstadt, Germany/Chair of Fluid Dynamics, Technische Universität Darmstadt, Germany, **Chair of Fluid Dynamics, Technische Universität Darmstadt, Germany

ABSTRACT

In numerical simulations of viscoelastic flow a breakdown in convergence often occurs for different computational approaches at critically high values of the Weissenberg number. This is due to two major problems concerning stability in the discretization. First, we have a mixed hyperbolic-elliptic problem weighted by a ratio parameter between retardation and relaxation time of viscoelastic fluid. Second, we have a convection-dominated convection-diffusion problem in the constitutive equations. We introduce a solver for viscoelastic Oldroyd B flow with an exclusively high-order Discontinuous Galerkin (DG) scheme for all equations using a local DG formulation with penalized fluxes in order to solve the hyperbolic constitutive equations [1] and using a streamline upwinding formulation for the convective fluxes of the constitutive equations [2] . While the saddle point problem of the Navier-Stokes system is of elliptic type, the constitutive equations modelling the viscoealstic behaviour are hyperbolic. The viscous parts of the momentum equations and of the constitutive equations are weighted by a ratio parameter. So depending on that parameter a change of type from elliptic to hyperbolic can occur and the numerical solution becomes unstable [2]. We use a local DG formulation following [1] to stabilize the system of equations including the constitutive equations for Oldroyd B fluid. The DG method allows jumps in the boundary conditions and preconditioning at the elemental level, appropriate flux functions for the edges can be chosen and additional velocity-stress compability conditions can be easily satisfied [2]. So the DG method is a promising method for convection dominated problems and is often used in combination with streamline upwinding for the convective terms of the constitutive equations of viscoelastic flow whereas the other terms are discretized using a Finite Elements ansatz. The successful implementation of both schemes is presented in an hp convergence study and first results are shown for various benchmark problems for viscoelastic flow. References: [1] Owens, R. Viscoelastic behavior of natural rubber with coarse-grained molecular dynamics

Byungjo Kim*, Junghwan Moon**, Maenghyo Cho***

*Seoul National University, **Seoul National University, ***Seoul National University

ABSTRACT

In this work, the viscoelastic properties of natural rubber are thoroughly investigated using a coarse-grained (CG) molecular dynamics (MD) simulation method. Due to the limitation of time and length scales in the MD simulation environment, it is challenging to assess the nature of viscoelastic of polymer materials with a computational approach. In that regards, CG MD offers an equivalent system with reduced degree of freedom by replacing a group of atoms with a corresponding bead particle. To describe the interactions between beads consisting of the system, the iterative Boltzmann inversion (IBI) is used for obtaining boned and non-boned potential. Herein, the time dependent shear relaxation modulus is calculated using the stress autocorrelation, and dynamic modulus (storage and loss modulus) is further calculated with the Fourier transformation in a complex domain. The viscoelastic behavior of natural rubber is studied considering a chain length effect. Plus, the influence of vulcanization of rubber is taken into account. To investigate more detailed viscoelastic nature of rubber, a wide range of temperature is considered for the present study. With the present work, the viscoelastic nature of rubber is understood by employing CG MD simulations which can enhance the scale of computation in terms of length and time. Further, this work can be extended to examine more complex polymeric system regarding the long-term physical nature or thermodynamic property. Keywords: Coarse-grained molecular dynamics, Rubber, Viscoelastic behavior. Development of Electricity-harvesting Piezoelectric Polymer Beams Vibrating in a Wind Flow Around Running Electric Vehicles Using Topology Optimization

Cheol Kim*, Changmin Park**, Jin-Young Yoon***

*Kyungpook National University, **Kyungpook National University, ***Hyundai Motor Company

ABSTRACT

An electric energy harvesting system that is installed on the surface of a vehicle has been developed in order to supply auxiliary electric power for EV (electric vehicles). The system consists of several thin piezoelectric polymer beams that are fixed at both ends and vibrating in an air stream around the running electric vehicle. The fluctuation of airflows around the harvesting beams attached to a car is analysed by using a CFD program. The characteristics of beam vibration and resulting generation of electricity are computed by using FEM. To maximize the amount of electricity generation from harvesting beams, the cross-sectional curvature and shape of a piezoelectric harvesting beam are optimized by the shape and topology optimization method. The structural vibration in a turbulent flow is considered during the optimization process simultaneously. For optimization, we develop a new electro-mechanical coupling coefficient and cost function for piezoelectric polymer. As results of analysis, a reasonable amount of electric power can be successfully harvested from passing airflow around a vehicle. The harvesting beam is fabricated and is installed on a car for validation tests. Real car driving tests for the harvesting system give good agreements with numerical predictions.

Tailoring the Stiffness of Tubular Structures through Auxetic Patterns

Do-Nyun Kim*, Kwang Je Lee**, Dongsik Seo***, Jeong Min Hur****

*Seoul National University, **Seoul National University, ***Seoul National University, ****Seoul National University

ABSTRACT

Auxetic materials are emerging mechanical metamaterials showing a negative Poisson's ratio that may have interesting geometrical and mechanical properties such as synclastic curvature in bending, high impact and indentation resistance, and tuneable dynamic properties for vibration isolation and wave control. While various deformation mechanisms and patterns have been proposed to achieve a negative Poisson’s ratio, little attention has been paid to its link to the fundamental mechanical properties of structures such as the stiffness. Here, we present a novel method to tailor the bending and torsional stiffness values of tubular structures by imposing auxetic cutting patterns on the tube. It is demonstrated that rational design of these patterns enables us to obtain a wide range of bending and torsional stiffness values without changing the cross-sectional shape, the size, and the material used. To illustrate, auxetic patterns based on the rigid-rotating-unit mechanism are employed and implemented on a cylindrical hollow tube by engraving alternating slits that divide the tube into rigid-rotating-unit-like and hinge-like sub-domains. Parametric studies for the geometric parameters of these patterns performed using the finite element method reveal the primary geometric parameters governing the tube stiffness. We also measure the tube stiffness experimentally for a set of patterned tubes, validating the simulation results and our design principles for stiffness control.

Auto Parameter Tuning in Topology Optimization Using Deep Reinforcement Learning

Dongjin Kim*, Jaewook Lee**

*Gwangju Institute of Science and Technology, **Gwangju Institute of Science and Technology

ABSTRACT

In this research, a basic auto parameter tuner has been developed to generate the target number of holes in topology optimization results using deep reinforcement learning [1]. This work aims to support engineers who suffer from parameter decision in topology optimization using deep learning techniques. In topology optimization problems, the unique solution is not guaranteed. To relieve numerical instability problems, various techniques have been proposed [2]. These techniques require careful control of many parameters. If improper parameters are used, it is difficult to get satisfactory optimization results. The parameters have been determined heuristically by designer's intuition till now. Therefore, this work proposes an auto parameter tuner constructed using deep reinforcement learning [1]. The deep reinforcement learning can be used for improving a quantified performance without the supervision [1]. In this research, the quantified performance is declared as a difference between the target and designed number of holes in the result of topology optimization. Here, the number of holes are calculated by the connected-component labeling [3]. For constructing the auto parameter tuner, a python code is developed. As a result, the developed parameter tuner generates the optimization result satisfying target number of holes. [1] Minh, V., et al, Nature(2015) 518: 529. [2] Sigmund, O. & Maute, K. Quantitative phase-field simulations for solidification microstructure with different preferred growth direction

Geunwoo Kim*, Munekazu Ohno**, Kiyotaka Matsuura***, Tomohiro Takaki****

*Hokkaido University, **Hokkaido University, ***Hokkaido University, ****Kyoto Institute of Technology

ABSTRACT

Preferred growth direction of metallic materials is one of important factors that have a great influence on solidification structures since it determines growth direction of dendritic structures. It has been understood and/or supposed, in general, that the preferred growth direction is exclusively determined by type of crystal structure. For instance, as the preferred growth direction in cubic crystals such as fcc and bcc is <100>. In recent years, however, it was revealed that the preferred growth direction of fcc alloy (Al-Zn binary alloy) changes from <100> to <110> by increasing concentration of the solute element.[1] The preferred growth direction of crystal is entirely determined by anisotropy of solid-liquid interfacial energy. The anisotropy of interfacial energy is described by two kinds of anisotropy strength, e1 and e2 that characterize <100> growth and <110> growth, respectively. The transition of preferred growth direction with alloy concentration indicates that e1 and e2 depend on the alloy concentration.[1] It is very important to understand the dependence of size and morphology of solidification microstructure on these parameters. However, details of morphological change and dependence on solidification conditions and alloy systems have not been clarified yet. Therefore, in this study, we investigated the morphological change of the isothermally- and directionally-solidified dendritic structures associated with transition phenomenon of the preferred growth direction. In this study, the simulation of isothermal and directional solidification in fcc binary alloys was conducted by using quantitative phase-field model[2] which can predict solidification structure with high accuracy. And the morphological change was investigated by changing e1 and e2 systematically. Effects of several parameters such as supersaturation, cooling rate, temperature gradient and alloy system, on the morphology were also investigated. [1] T. Haxhimali, A. Karma, F. Gonzales, and M. Crack Self-healing During the Relaxation

Hokun Kim*, Sung Youb Kim**

*UNIST, **UNIST

ABSTRACT

Unexpected behaviors of materials are critical for designing the structures which can lead to undesirable results. Hence, it is important to understand the behaviors of materials. However, the mechanical responses of nanomaterials are different from those of bulk counterparts causing unexpected behavior. For examples, nanomaterial becomes flaw insensitive under the critical size [1], small enough nanowire undergoes a phase transformation [2], and the surface stress affects the instability of nanomaterials [3]. Therefore, identifying the unique behavior of nanomaterial is significant for nanotechnology. Using molecular dynamics simulations with embedded atom method (EAM), we observed that cracks are self-healed during the relaxation of surfaces. Crack surfaces are closed (re-bonded) without any external force applied, leaving crack tip as a dislocation. Centered and edged cracks were investigated with different sizes and aspect ratios with various materials that have different amount of surface properties. Other unexpected behaviors of nanoscale cracks are discussed specially emphasized on the effect of surface relaxation. 1. Gao, H., Ji, B., Jager, I. L., Arzt, E. & Fratzl, P. Level-set Based Shape Optimization Using Polyhedral Elements

Hyun-Gyu Kim*, Son Nguyen-Hoang**

*Seoul National University of Science and Technology, **Seoul National University of Science and Technology

ABSTRACT

In the level-set based shape optimization, the structural boundary is implicitly represented by the zero-level set of an level set function and a velocity field is computed based on a shape sensitivity analysis to iteratively update the new shape of the structures by mathematically solving the Hamilton-Jacobi equation. Most of level-set based shape optimization methods utilize a fixed regular mesh for both of the level set function evolution process and the structural domain analyses. Due to the inexactitude of a mesh for the structural model, the finite element method cannot be implemented directly for the structural analyses. In this study, the evolution of geometric shapes based on level-set based shape optiomization is obtained by cutting a background hexahedral mesh. The zero isosurace of a level set function split a background hexahedral mesh. Polyhedral elements are generated at the boundaries of the split domains by the marching cube algorithm. The trimmed hexahedral meshes are partitioned into an interior domain with negative level set values and an exterior domain with positive level set values. In the level-set based shape optimization using trimmed hexahedral meshes, polyhedral elements at their boundaries play an important role for capturing the structural domain. We recently proposed an efficient scheme for constructing shape functions on polyhedral domains with non-planar faces by using MLS approximation. The polyhedral shape functions satisfy the required properties of conventional finite element method such as continuity within elements, partition of unity, linear completeness, inter-element compatibility and the Kronecker-delta property. The trimmed hexahedral meshes can provide an efficient and effective tool for level-set based shape optimization problems.

Finding Nearest Helpers for Cardiopulmonary Rescuscitation Using Defibrillators

Jaewon Kim*, Dongsoo Han**

*KAIST, **KAIST

ABSTRACT

If patients in heart attack are fell down and unable to move by themselves, they should be rescued in a hurry. The brains of the heart-attacked patients are damaged unless appropriate action is taken within 5 minutes. To help the fast rescue activity, hundreds of thousands of defibrillators have been deployed in many places these days. Nevertheless, taking first-aid measures for cardiopulmonary resuscitation for heart-attacked patients within 5 minutes is not a simple task. This paper proposes a technique to rescue heart-attacked patient using nearby defibrillators. This paper assumes that a heart-attacked patient asks a rescue service to a remote service center which is located far away from the patient. The patient usually loses consciousness immediately after the rescue request. Then the remote service center has to identify nearby people or rescue service members to help the hear-attacked patient. First, it estimates the patient's location and requests nearby special purpose access points (APs) to capture probing signals from smartphones. Then a server fetches the captured probing signals and identifies devices with the probing signals. The server determines a person who can rescue the patient and sends a message to help the patient. An experiment performed on the 7th floor, N1 building, KAIST with ten specially purpose APs. The experiment revealed that the scenario could be effective if the special purpose APs were properly installed in a service area.

Stress Based Creep Life Evaluation of Super304H Using Small Punch Creep Test

Jeong Hwan Kim*, Uijeong Ro**, Moon ki Kim***

*sungkyunkwan university, **sungkyunkwan university, ***sungkyunkwan university

ABSTRACT

Ultra-supercritical power plant operating at high pressure and high temperature has advantage of high-efficiency. The super-heater and the re-heater must endure such harsh operating conditions. Metals exposed to high temperature usually fail by creep. Therefore, it is important to understand the creep to design a safe power plant. Creep phenomenon shows a plastic deformation of material in time even when it is subjected to a low stress below macroscopic yield stress. The conventional uniaxial creep test was mainly used to evaluate the creep life of the material. However, it has shortcomings that a specimen cannot be taken from a plant in-service without damage. And also, it usually takes a long test time. Small punch creep test overcomes these shortcomings by using a small sheet of specimen which is 1/200 in size compared with uniaxial creep test specimens. For this reason, the specimen can be sampled from an in-service power plant. Also, it consumes relatively less time than the uniaxial creep test. However, it was neglected in the industrial field because it is difficult to evaluate the creep life using small punch creep test than uniaxial creep test. This is because conventional life evaluation method of small punch creep test must be preceded by uniaxial creep test. Considering the aforementioned advantages, a creep life evaluation method using only small punch creep test is needed in order to reduce cost and time. In this study, a creep life evaluation method of small punch creep test was proposed. Stress based creep life evaluation method can evaluate creep life only using small punch creep test result without uniaxial creep test. Super304H which is one of the main material of ultra-supercritical power plant was used as the test specimen. And small punch creep test was performed at 650 degrees of Celsius. Finally, the suggested method is verified through Larson-Miller model.

Modeling of 3D Printed Carbon Nanotube-Thermoplastic Polyurethane Composites for Piezoresistive Pressure Sensors

Ji Hoon Kim*, Jaebong Jung**, Myoung-Seok Kim***, Dae-Hyeong Kim****

*Pusan National University, **Pusan National University, ***Pusan National University, ****Seoul National University

ABSTRACT

In order to design flexible pressure sensors with high sensitivity, a multi-physics computational model for piezoresistivity was developed. The anisotropic change of piezoresistivity upon deformation was analyzed experimentally and numerically using a 3D resistive network model. Then a phenomenological piezoresistivity model was developed to represent the piezoresistive behavior of conductive polymer composites. Carbon nanotube-thermoplastic polyurethane (CNT-TPU) composites were produced using 3D printing and used for validation of the proposed model. The effect of processing conditions and heat treatment on sensitivity was analyzed.

Correlation Between Microstructural Characteristics and Properties of Cement Paste with Variable Void Distributions

Ji-Su Kim*, Tong-Seok Han**

*Yonsei University, **Yonsei University

ABSTRACT

Concrete is composed of void and solid phase with hydration products [1]. Porous material generally has a material response related to its porosity. For instance, the strength of concrete is well known for being proportional to cube of gel-space ratio (e.g., Powers' model). Microstructural characteristics of cement paste include connectivity and continuity of voids as well as the porosity, and the continuity of voids has a relation to the response of materials. In this study, the material properties are described as a function of porosity and void distribution of cement paste. The correlation between microstructural characteristics and material properties is investigated using cement paste specimens with various water/cement ratio. To prepare the specimens, five water cement ratios (w/c) of cement paste are designed as 0.3. 0.4, 0.5, 0.6, and 0.7. Each specimen has a different microstructural characteristic, e.g., porosity and void continuity. In order to characterize the microstructure of the material, micro-CT images are taken and binarized into voids and solid phases [2]. A three-dimensional finite element model is generated from CT images, and a lineal-path function is used to characterize the void continuity among low-order probability functions [3]. The area of the lineal-path function is used as a quantified parameter of the void continuity. The material properties of cement paste are evaluated for strength and stiffness through compression test and nanoindentation. The crack phase field model with input parameters obtained from the experiments is performed. From this study, the relations between microstructural characteristics and material responses of cement paste are suggested in a simple functional form. [1] Mindess, S., Young, J. F., & Darwin, D. Design of a Honeycomb Panel for Protection of a Steel Columns Subjected to Vehicle Collision

Jinkoo Kim*, Hyungoo Kang**

*Sungkyunkwan University, **Sungkyunkwan University

ABSTRACT

ABSTRACT This study investigates the performance of aluminum honeycomb panels attached to the face of a steel column for reducing local damage caused by automobile collision. A method for estimating the dynamic plateau stress of honeycomb was proposed based on mass and velocity of the vehicle. In addition, the stress-strain histories were linearized to easily estimate the amount of energy absorbable by the honeycomb structure. To verify the impact energy absorption capability of the honeycomb panel designed with the proposed method, a vehicle collision analysis was carried out using an 8-ton truck. According to the analysis results, the honeycomb panel could be effective in decreasing the displacement of the structure due to vehicle collision. It was also shown that the energy absorption capacity of the honeycomb panel estimated by the proposed method was found to be quite similar to the value obtained from the collision analysis. Key words : Vehicle impact, FE analysis, Honeycomb panel Acknowledgement This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(NRF-2016R1D1A1B03932880)

Free Vibration of Thin-Walled Beams with Discontinuously Varying Cross-Sections

Jun-Sik Kim*, Gijun Lee**

*Kumoh National Institute of Technology, **Kumoh National Institute of Technology

ABSTRACT

We investigate the frequency variation due to the interface in thin-walled beams. In order to properly consider the interface effect, we calculate the warping functions of the interface by employing the constrained cross-sectional eigenvalue analysis. The formulation starts with an asymptotic formulation which is applied to the Koiter-Sanders' shell theory built upon the general tensor-based coordinate system. One-dimensional finite element analysis for the cross-section of thin-walled beams is set up first, and then it is extend to the interface between two different cross-sections. The formulation takes the form of an eigenvalue problem with Lagrange's multipliers that are used to enforce the displacement continuity, rigid-body constraint, and orthogonality conditions to the fundamental warping functions. The results obtained will be compared to those of commercial software and will be discussed in terms of the importance of interface warping functions.

Numerical Simulation of Butt-welding Considering Metallic Phase Transformation

Kyu Won Kim*, Moon Kyum Kim**, Woo Yeon Cho***

*Yonsei University, **Yonsei University, ***POSCO

ABSTRACT

Residual stresses may occur the deterioration of steel structure, buckling strength and fatigue strength, and these may cause damage to the integrity of the structure. In addition, tensile residual stress occurred at the centerline of the welding part increases the crack propagation force and decreases the resistance of the structure to brittle failure. it greatly affects the fracture behavior of the welded structure. Therefore, the prediction and the evaluation of the residual strain and residual stress due to the welding are very important for the quality and life prediction of the steel structure. The distribution of residual stresses due to welding was affected by various factors such as welding parameters, types, sequence, component type, component materials and component size. The temperature variation of metallic material in the welding process causes a phase transformation of the metal. The martensitic transformation such as volumetric changes of austenitic and martensitic that caused by rapid cooling to room temperature causes significant volume changes and yield stress changes. This paper presents a coupled three-dimensional (3-D) thermal-mechanical finite element analysis to simulate residual stresses due to butt welding considering metallic phase transformation. The heat of the welding arc is modeled by a body heat flux with a double ellipsoidal distribution proposed by Goldak and Akhlagi (2012), and the moving heat source is implemented by the ABAQUS subroutine DFLUX model. In the numerical model, phase transformation plasticity is also taken into account.

Universal Meshes for Domains with Piecewise C2-regular Boundaries

Kyuwon Kim*, Adrian Lew**

*Stanford University, **Stanford University

ABSTRACT

The idea of a universal mesh is that a background mesh can be used to achieve conforming meshes for a family of domains, which allows it to be applicable for domains with evolving boundaries. Rangarajan introduced an algorithm to achieve conforming meshes for domains with C2-regular boundaries under certain conditions, but its application on domains with more general boundaries, such as with corners, has not been studied yet. One necessary condition to achieve a valid mesh is that the projection of positive edges onto the boundary must be guaranteed to be a homeomorphism. We introduce an algorithm to select positive edges for domains with piecewise C2-regular boundaries in a manner that their projection is a homeomorphism. We introduce a theorem which assures that the projection of positive edges is sure a homeomorphism, when certain restrictions are given on the mesh. In our approach, we use the closest point projection and focus on how to choose an appropriate set of positive edges. Instead of selecting positive edges for the whole curve, the boundary is divided into a finite number of C2-continuous curves and treated separately. The positive side and positive edges are chosen individually for each curve to guarantee the projection to be a homeomorphism. Given the local maximum curvature of the curve and the maximum angle of the mesh, we also introduce an upper bound for the meshsize to guarantee the algorithm to work for domains with piecewise C2-regular boundaries.

ABSTRACT

Lithium ion battery has led the secondary battery market. It is also expected to be widely used from portable IT devices to high capacity applications such as energy storage system and electric vehicles in the near future. To satisfy future demands, Ni1/3Co1/3Mn1/3O2 (NCM) has been suggested as an alternative anode material because of its high rate of discharge/charge and stability. Electrochemical performance of NCM is determined by small size with a narrow particle size distribution (PSD) and spherical morphology. Taylor-couette crystallizer (TCC) is a highly effective manufacturing device to prepare uniform NCM particles using Taylor vortex. However, controlling the quality of a product is still ambiguous because of a short reaction time and complex interactions between hydrodynamics and manufacturing parameters. To overcome this obstacle, computational fluid dynamics is employed based on population balance equations. The coupled numerical problem has been solved by standard method of moments, discretized population balance, Monte Carlo simulation, and quadrature method of moments. Each previous study is limited by size-independent coefficients, a lot of class requirement, difficulty in applying to a real reactor, and a monotonous PSD. In this paper, a new numerical approach for agglomeration/deagglomeration is introduced to predict the change of PSD with an individual particle in TCC. Firstly, based on immersed boundary method, a unit cell is prepared as a Taylor vortex to implement core mechanisms for particle growth. In the unit cell, each particle is transported by Brownian motion or shear flow resulting in collisions. Then, the state of each particle is determined by collision efficiency [1], maximum agglomerates diameter [2], and breakage potential function for the next increment. These coefficients are updated by taking into account hydrodynamic and particle characteristics. After that, multiple cases of average particle size are tried to predict final average size and PSD. As a result, the average particle size and PSD is obtained for various input cases. A growth rate induced by the change of average size indicates whether the dominant phenomenon of the system is agglomeration or deagglomeration. A positive value of the growth rate implies an increase of average particle size and vice versa. By finding the size with a growth rate of zero, the final particle size is predicted. This prediction result shows a good agreement with the experimental data. 1. Balakin B. et al., Chem. Eng. Sci. 68, 305, (2012). 2. Kim, J. M. et al., W.S., Colloid. and Surf. 385, 31, (2011).

ABSTRACT

The use of computational model for predicting the performance of engineering products has been largely increased due to the fast growth in computing power. The accuracy of computational results from high-fidelity model is now a great concern for engineers. In order to improve the accuracy of computational models, uncertainty in various material properties has to be considered. To address such issues, statistical model calibration has been developed[1], which increases the predictive capability of computational models by identifying and determining the uncertainty of material properties based on the results from both the experiments and the computational models. This method, has been recently employed to improve the high-fidelity electromechanical model of piezoelectric energy harvester[2]. To the best of our knowledge, however, the multivariate responses in the statistical model calibration has never been considered, which can be an important factor to improve the accuracy of the computational model. This paper proposes a statistical model calibration method, which considers multivariate responses of piezoelectric energy harvester: natural frequency and output voltage. The proposed method is used to perform a probabilistic design of piezoelectric energy harvester and the results are compared with the results from the previous statistical model calibration.

Construction of ITZ Specimens with Functionally Graded Microstructure by Extended Stochastic Optimization and Evaluation of its Properties

Se-Yun Kim*, Tong-Seok Han**

*Yonsei University, **Yonsei University

ABSTRACT

Concrete can be divided into three phases which are aggregates, bulk cement paste and interfacial transition zone (ITZ). The ITZ is located between the aggregates and the bulk cement paste. The void phase of the ITZ has a gradient distribution depending on the distance away from the aggregate, which means the ITZ is not only a functionally graded material but also a critical section to determine properties of concrete. However, information on the ITZ microstructure is difficult to obtain compared with bulk cement paste microstructure. In this study, three kinds of the bulk cement paste are used to construct virtual ITZ specimens. The low-order probability functions are used to quantify the characteristics of the void distributions over the bulk cement paste specimens in three orthogonal directions [1]. The characteristic of the microstructure is subdivided into clustering, continuity and connectivity of void clusters, and all of the characteristics are used as resources to construct the virtual ITZ specimens using a stochastic optimization. The stochastic optimization is extended to incorporate the information of the void gradient, and the iteration process in the stochastic optimization is modified to minimize the computational resources. Using the microstructures reconstructed from the extended stochastic optimization method, the properties of the ITZ in concrete can be evaluated a virtual loading tool, e.g., a finite element method. The evaluated elastic modulus, heat conductivity and permeability in three orthogonal directions show the anisotropy of the ITZ and a good correlation between the properties and the void distribution gradient. ABSTRACT

In the computational approach, efficiency and accuracy are the main aims of reduced-order modeling (ROM). Numerous techniques have been studied for the last several decades, but those are still main issues. Based on the motivation, we here suggest an integrated model reduction algorithm of Craig-Bampton (CB) component mode synthesis (CMS) method [1], which is one of the widely used ROM techniques in structural dynamics society. The proposed algorithm consists of three phases: important mode selection, CB based model reduction and a posteriori error estimation. In this work, we use a priori mode selection scheme [2], which was recently developed to precisely rank dominant substructural modes. The mode selection scheme was derived by using a moment-matching approach and a consistent perturbation expansion [2]. To evaluate the accuracy of a reduced model, a posteriori error estimator recently developed by Kim et al. is also employed, which can accurately predict relative eigenvalue errors of a reduced model without any information of reference eigenvalues [3]. Combining the techniques, we propose an integrated model reduction algorithm, and demonstrate its feasibility through several numerical examples. [1]. Craig, R., & Bampton, M. (1968). Drag Effect on the Motions of Dislocations and Grain Boundaries in Nanoscale

Soon Kim*, Jaehyung Hong**, Sung Youb Kim***

*Ulsan National Institute of Science and Technology, **Ulsan National Institute of Science and Technology, ***Ulsan National Institute of Science and Technology

ABSTRACT

It is well known that plastic behaviors of materials are governed by collective motion of dislocations and interactions of them with other defects. A mobility and reaction properties of the dislocation are decided by its core structure. The core makes the dislocation have nonlinear properties, which cannot be explained by classical linear elasticity theory. Furthermore, it has been reported that the core induces unexpected behaviors in nanoscale [1]. To understand the fundamentals of material plasticity, thus, it is necessary to characterize behaviors of the dislocation core by priority. Especially, in case of metallic materials, the motion of dislocations is significantly disturbed by grain boundaries, and their interactions increase ductility of the materials. In a sense that most metals used in industry are polycrystalline, the influence of grain boundaries on material plasticity must be emphasized. Despite of the importance of the grain boundaries, however, the researches of the grain boundary have been focused on phenomenological approaches rather than systematic analysis due to difficulty caused by large degree of freedom to define the grain boundaries. In this work, we employ both atomistic simulation and theoretical approach to describe motion of various low angle grain boundaries by expanding dislocation theory in nanoscale. Firstly, we observed unusual behavior that externally applied stress is reduced inside of nanoscale materials while single dislocation is in motion, which is defined stress-drop behavior [1]. By developing simple analytic equation based on discrete lattice dynamics theory, we can explain this unusual behavior. Furthermore, we also observed that the stress-drop behavior appears during motion of the grain boundaries under external stress. Unlike single dislocation, however, not only the stress-drop but also curvature of grain boundaries were observed during their motions. And our result proves that the curvature is maintained by phonon drag induced by scattering of external loading and interaction between dislocations which consist the grain boundary during its motion.

Comparison between Various Approximations for Free Energy Calculation in Partitioned-Domain Methods

Woo Kyun Kim*, Ellad Tadmor**

*University of Cincinnati, **University of Minnesota

ABSTRACT

Partitioned-domain methods are multiscale approaches that divide a system into an atomistic region where full-atomistic resolution is retained, and a continuum region represented by a coarse-grained finite element model with local constitutive relations. At finite temperature, the constitutive relation corresponds to the Helmholtz free energy of a strained infinite crystal. This study examines several approximation methods for free energy calculations used in variations of the quasicontinuum (QC) method: (1) The quasi-harmonic (QH) approximation in which the potential energy is expanded to second order and the free energy is integrated analytically; (2) the local-Harmonic (LH) approximation, which is similar to QH but with off-diagonal terms in the Hessian matrix neglected; (3) the maximum entropy (max-ent) formalism based on ideas from information theory. To test the accuracy of these methods, all three have been implemented within a single framework. The results for various problems including thermal expansion, simple shear, and a Lomer dislocation dipole will be presented. In addition, the effect of “ghost forces” (numerical artifacts appearing at the continuum-atomistic interface) in a hot-QC simulation is investigated. For static QC, ghost forces can be addressed using a dead-load correction. The effectiveness of this approach in hot-QC is tested.

Multiscale Indentation and Bending Simulations of Mono-layered Graphene in Elastic Regime

Yongwoo Kim*, Keonwook Kang**

*Department of Mechanical Engineering, Yonsei University, Republic of Korea, **Department of Mechanical Engineering, Yonsei University, Republic of Korea

ABSTRACT

In this study, we investigated mechanical behaviors of mono-layered graphene under indentation [1] and bending using molecular statics (MS) simulations and finite element analysis (FEA). We tested circular graphene sheet with the Adaptive Intermolecular Reactive Empirical Bond Order potential (AIREBO) [2]. Changing thickness of graphene in FEA, the force-indentation depth curve was compared with that in MS. And we found an effective thickness where both results match in elastic regime. Additionally, deflection curve and induced Cauchy stress in graphene sheet were compared, too. Presented results demonstrate that the proposed method could provide a valuable tool for studying the mechanical behavior of mono-layered graphene sheet using FEA. [1] Lee, C., Wei, X., Kysar, J. Rigid-body Mechanism Synthesis by SBM (Spring-connected Rigid Block Model) Based Topology Optimization

Yoon Young Kim*, Seok Won Kang**

*Department of Mechanical and Aerospace Engineering, Seoul National University, **Department of Mechanical and Aerospace Engineering, Seoul National University

ABSTRACT

In spite of great success of the topology optimization in designing load-carrying structures, its use in synthesizing motion-generating rigid-body mechanisms is less active. There are several issues to be resolved to advance the topology optimization based mechanism synthesis, but in this presentation, we will be focused mainly on the ground modeling issue. Especially for numerically efficient gradient-based topology optimization based synthesis, there are two ground models available, the revolute joint-connected link model and the zero-length spring-connected rigid block model (SBM). Unlike the link ground model only allowing revolute joints, we will show that the SBM developed in [1,2] allows the presentation of revolute, prismatic, and other types of joints when the spring stiffness takes on its upper or lower bound value. Because the stiffness can be interpolated as a function of a real design variable, the use of a gradient-based optimizer is readily possible. After the underlying concept of the SBM suitable to represent only revolute joints, an alternative model method called, the double-spring connected rigid block model (D-SBM) will be presented in order to represent general joints. Also, a method to deal with revolute and prismatic joints only is presented and its successful application in the design of a robotic rehabilitation device by the SBM-based topology optimization method will be presented. Extended Analytic Model of Staggered Platelet Structure and Its Application to 3D Printing Technology

Youngsoo Kim*, Seunghwa Ryu**

*Department of Mechanical Engineering, Korea Advanced Institute of Science and Technology (KAIST),
**Department of Mechanical Engineering, Korea Advanced Institute of Science and Technology (KAIST)

ABSTRACT

There have been many studies to understand and utilize the superior mechanical properties of nacre with moderate stiffness and high toughness. The load transfer mechanism in the unique ‘brick and mortar’ structure of the nacre has been intensively analyzed and its structural features has been mimicked by various manufacturing methods such as 3D printing. However, due to the limited applicability of most analytical models and the limitation in the 3D printers, it has been difficult to theoretically predict and design the propertied 3D printed structures. In this study, we improve the analytic models to predict the effective elastic properties of the ‘brick and mortar’ structure for a wide range of constituent materials and geometric ratios by correctly accounting volume (Area for 2D) average concept. In addition, we also reveal the effect of the printing direction and thickness on the 3D printed composite materials. We show that our extended analytic model accurately predict the properties of 3D printed composite when using the manufacturing-condition-dependent material properties as input. Furthermore, we suggest a new possible design to increase the toughness of composites. Our studies reveals the origin of discrepancy between theory and 3D printed structures and enable a rational design of nacre-inspired structures.

Strain-rate Dependent Microplane Constitutive Model for Dynamic Fracturing and Comminution of Concrete during Projectile Impact

Kedar Kirane*, Zdenek Bazant**

*Stony Brook University, **Northwestern University

ABSTRACT

While numerous studies have dealt with dynamic crack propagation in concrete, they have not led to a macroscopic continuum model usable in FE analysis. Such a model was recently developed and is presented here. The model is based on the recently developed theory of comminution according to which comminution of concrete under high-rate impact loading is driven by the release of the local kinetic energy (rather than the strain energy) of the shear strain rate field. This theory yields expressions to calculate the particle size and the additional kinetic energy density that must be dissipated in finite-element codes. In previous research, it was dissipated by additional viscosity, in a model partly analogous to turbulence theory. Here it is dissipated by scaling up the material strength. Microplane model M7 is used and its stress–strain boundaries are scaled up by factors proportional to the ?4/3rd power of the effective deviatoric strain rate and its time derivative. The crack band model with a random tetrahedral mesh is used and all the artificial damping is eliminated. The scaled M7 model is seen to predict correctly the crater shapes and exit velocities of projectiles penetrating concrete walls of different thicknesses. The choice of the finite strain threshold for element deletion criterion, which can have a big effect, is also studied.

Efficient Simplicial Finite Elements Via Bernstein Polynomials

Robert Kirby*

*Baylor University

ABSTRACT

The mathematical power offered by high-order finite element methods is all-too often realized at a high computational cost, especially on simplicial meshes where basis functions lack tensor product structure. However, recent work on Bernstein polynomials has led to efficient algorithms for many fundamental finite element kernels. Algorithms that evaluate load vectors and the (action of) finite element matrices with optimal complexity are now know, including for H(div) and H(curl) spaces. Additionally, optimal algorithms for interpolation and polynomial projection in the Bernstein basis, which are also required at various stages, can be given in terms of block-structured linear algebra. This structure depends intricately on the details of Bernstein polynomials. Finally, the nonnegativity of the Bernstein basis has been suggested as a pathway to enforce positivity for higher-order bases in transport or other applications with hard constraints. This talk will summarize the state of the art for Bernstein polynomials and include numerical examples.

NOx Prediction of a Natural Gas and Hydrogen Mixed-combustion-type Gas Turbine Combustor

Ryosuke Kishine*, Nobuyuki Oshima**, Kohshi Hirano***, Takeo Oda****

*Hokkaido University, **Hokkaido University, ***Kawasaki Heavy Industries, Ltd., ****Kawasaki Heavy Industries, Ltd.

ABSTRACT

In pursuit of a reduction in environmental loading, gas turbine combustors that use a hydrogen-enriched fuel instead of pure natural gas have entered practical service. In such a new attempt, numerical simulation is very effective for more efficient development because it can easily perform parametric studies. In our previous study [1], a numerical analysis was performed on a natural gas and hydrogen mixed-combustion-type gas turbine combustor using large-eddy simulation and a multi-scalar flamelet approach. Three conditions were analyzed with different introduction amount of hydrogen, and the tendencies of the simulation results qualitatively agreed with the knowledge in the experiments. In the current study, we aim to investigate an applicability of the numerical method for the turbulent mixed-combustion field by comparing the simulation results of NOx emission with the experimental ones as a next step. The calculation object was the combustor of an L30A-DLE gas turbine, developed by Kawasaki Heavy Industries, Ltd. This combustor has a diffusion pilot burner, a premixed main burner, as well as a premixed supplemental burner and cooling air inlets. In order to conduct a quantitative evaluation, the reproducibility of the shape for the burners and the other parts was improved compared to our previous research. The number of elements therefore increased from about 20 million to 30 million. Calculations were conducted under two different operating conditions of the same load. The design fuel ratio of the two-type premixed burners were different in each case. Because NOx is considered as a passive scalar in combustion calculations, it can be predicted separately from combustion calculation by LES. This idea about NOx prediction is very effective in decreasing the calculation cost. The simulated distributions of the NOx production rate well captured the difference between the two conditions. These results suggest that by setting the higher fuel ratio of the supplemental burner, NOx emissions are reduced along with the decrease in the high temperature region. In our presentation, we will show the quantitative comparison results of simulated values and experimental ones about NOx emissions. At the same time, we are planning to examine the validity of this NOx prediction method by comparing it with the results of the normal prediction method. The Influence of Binder Mobility to the Viral Entry Driven by the Receptor Diffusion

Sandra Klinge*, Tillmann Wiegold**, Gerhard A. Holzapfel***

*TU Dortmund University, **TU Dortmund University, ***Graz University of Technology, Norwegian University of Science and Technology

ABSTRACT

The current presentation deals with the simulation of the viral entry into a cell. There are two dominant mechanisms typical of this process: the endocytosis und the fusion with the cellular membrane. However, we only focus on the first scenario. To this end, we consider a virus as a substrate with a constant concentration of receptors on the surface. Differently, the concentration of receptors of the host cell varies and these receptors are free to move over the membrane. When the contact with the cell surface has been achieved, the receptors start to diffuse to the contact (adhesion) zone. The membrane in this zone inflects and forms an envelope around the surface of the virus. This is the way the newly formed vesicle imports its cargo into the cell. In order to simulate the process described, we assume that the differential equation typical of the heat transport is suitable to simulate the diffusion of receptors. Additionally, we formulate two boundary conditions: First, we consider the balance of fluxes on the front of the adhesion zone. Here, it is supposed that the velocity is proportional to the gradient of the chemical potential. The second subsidiary condition is the energy balance equation depending on four different contributions: the energy of binding receptors, the free energy of the membrane, the energy due to the curvature of the membrane and the kinetic energy due to the motion of the front. The differential equation itself along with two boundary conditions forms a well-posed problem which can be solved by applying a direct method, for example the finite difference method. The talk also includes numerical examples showing the distribution of receptors over the membrane as well as the motion of the front of the adhesion surface. In particular, the influence of the mobility of receptors has been studied.

A Computational Framework for Scale-bridging in Multiscale Simulations and Its Applications to Modeling of Energetic Materials

Jaroslaw Knap*, Kenneth W. Leiter**, Richard Becker***, Brian C. Barnes****

*U.S. Army Research laboratory, **U.S. Army Research laboratory, ***U.S. Army Research laboratory, ****U.S. Army Research laboratory

ABSTRACT

Over the last few decades, multiscale modeling has become a dominant paradigm in materials modeling and simulation. The practical impact of multiscale modeling depends, to a great extent, on its ability to utilize modern large-scale computing platforms. However, since there are no general numerical and computational frameworks for multiscale modeling, the vast majority of multiscale material models or simulations are developed on a case-by-case basis. We seek to formulate an adaptive computational framework for multiscale modeling. We do not intend to develop a specific method for multiscale simulations, but instead, aim to develop a broad and flexible computational framework for designing and developing such simulations. Our focus is primarily on new scalable numerical algorithms applicable to a wide range of multiscale modeling applications and, more specifically, to scale-bridging. These algorithms fall into one of the three areas: i) adaptive computational strategies for multiscale modeling, ii) algorithms for scale-bridging in multiscale modeling, and iii) algorithms for development of surrogate models to reduce the computational cost associated with multiscale models. We present a formulation of our computational framework and describe our progress towards development of a two-scale model of an energetic material utilizing it.

Modeling Intragranular Misorientation, Grain Fragmentation, and Associated Effects on Mechanical Fields and Texture Evolution in Polycrystals Using the Viscoplastic Self-Consistent Framework

Marko Knezevic*, Rodney McCabe**, Miroslav Zecevic***, Ricardo Lebensohn****

*University of New Hampshire, **Los Alamos National Laboratory, ***University of New Hampshire, ****Los Alamos National Laboratory

ABSTRACT

In recent works, we reported the methodology to calculate intragranular fluctuations of the instantaneous lattice rotation rates (Lebensohn et al., 2016) and associated misorientation distributions developing inside each grain representing a polycrystalline aggregate within the mean-field viscoplastic self-consistent (VPSC) homogenization (Zecevic et al., 2017). The methodology is based on the second moment of intragranular stresses calculated by the VPSC model. This paper advances the methodology to incorporate the effect of the intragranular misorientations on stress fluctuations. Furthermore, the fluctuations of plastic spin are defined as a function of not only the stress fluctuations but also the intragranular misorientations. These advances facilitated the development of a grain fragmentation (GF) model within VPSC, which is conceived within the crystal orientation space. The overall model is termed GF-VPSC. Case studies including simple tension and plane-strain compression of face-centered cubic polycrystal deformed to large strains are used to illustrate the utility of the developed model. The predictions of intragranular misorientation distributions and texture evolution are compared with full-field calculations and experiments. Good agreement is obtained for the intragranular misorientation distributions and, as a result, more accurate modeling of texture evolution is facilitated by the new model relative to the standard VPSC. Since the developed intragranular misorientations act as driving forces for recrystallization, the novel GF-VPSC is shown to enable coupled modeling of microstructure evolution during deformation and recrystallization in a computationally efficient manner. Butterflies in Layered Media

Nicholas Knight*, Michael O'Neil**

*NYU-Courant, **NYU-Courant

ABSTRACT

We present an algorithm for electromagnetic scattering calculations in layered media by use of butterfly-accelerated Sommerfeld integrals. In the time-harmonic setting, representing electromagnetic fields by generalized Debye sources (and their Fourier transforms) along layered media interfaces efficiently decouples several unknowns, and leads to a representation whose evaluation is amenable to acceleration via a butterfly algorithm. When coupled with an iterative solver, the corresponding integral equation formulation can be efficiently solved.

**Solid Mechanics, Darmstadt University of Technology, Frankziska-Braun-Str. 7, 64287 Darmstadt, Germany

ABSTRACT

The computation of interlaminar stresses is essential for the design of layered composite structures. While solid elements are able to compute these stress states, they represent a numerically expensive approach. This work deals with layered shells subjected to static loading for prediction of interlaminar stresses. The underlying shell theory is based on the Reissner-Mindlin kinematics with an inextensible director field. Additional degrees of freedom for in-plane warping and relative displacements in thickness direction are introduced. These displacements are interpolated with layerwise cubic functions, which are constant within one element and discontinuously over its boundaries. The resulting shell element is applicable for geometrically and physically nonlinear problems. Further a multifield functional based on the Hu-Washizu functional is introduced. Here the associated Euler-Lagrange equations include the usual global shell equations in terms of stress resultants, the local equilibrium in terms of stresses, the geometric field equations and the constitutive equations. In addition the functional contains a constraint, which enforces the correct shape of the warping function through the thickness [1]. The finite element formulation is based on the isoparametric concept for four-node quadrilateral shell elements. The elimination of independent stresses, warping and Lagrange parameters on element level leads to a mixed hybrid shell element with the standard 5 or 6 degrees of freedom per node. This is a fundamental characteristic, since it is possible to use standard geometrical boundary conditions. Therefore the element can be applied to complex geometrical problems. The transverse stresses are continuous at layer boundaries for linear elastic problems. An interface to three-dimensional material laws is part of the element formulation, too [2]. This allows together with the determination of thickness normal stresses the computation of delamination effects of layered laminates. Results of several examples will be shown and compared to reference solutions. Here geometrically nonlinearity, as well as physically nonlinear material behavior is considered. In comparison to 3d models, the present shell element needs only a fractional amount of computing time. References: [1] F. Gruttmann, W. Wagner, G. ABSTRACT

Rupture of a cerebral aneurysm often leads to a devastating event with high mortality and long term disability. In the abdominal artery, celiac trunk stenosis tends to generate multiple panceaticoduodenal arcade aneurysms. Hemodynamic factors play an important role in aneurysmal formation, growth, and rupture. Hemodynamic simulations with patient-specific arterial geometry have been performed to calculate hemodynamic forces such as wall shear stress (WSS) and WSS gradient. The three-dimensional (3D) arterial bend can be characterized as curvature and torsion along arterial centerline. Lauric et al. [1] investigated the relationship between the curvature along internal carotid artery (ICA) with aneurysm and hemodynamic forces. On the other hand, concavity and convexity on aneurysmal surface can be characterized as Gaussian and mean curvatures. The purpose of this study is to characterize both vascular geometry of peri-aneurysmal environment and aneurysmal geometry. We have been developing an image-based 3D geometrical modeling system, V-Modeler [2], to investigate quantification of arterial morphological changes. The modeling system consists of five functions: 1) segmentation of arterial lumen; 2) extraction of arterial centerlines; 3) surface reconstruction; 4) calculation of geometric parameters; and 5) tracking of arterial geometry. The centerline and surface are represented as spline functions in order to remove influence of noise in medical images. Curvature and torsion along the centerline are calculated from the spline function. In addition, we develop a spline surface fitting method using correspondence between arterial centerline and surface. The method consists of: - Triangular spline surface representation [3] considering topological changes in arterial bifurcation and aneurysm, - Construction of 1-to-N index corresponding table between centerline and surface based on boundary representation, - Arterial surface smoothing based on triangular spline surface fitting with the corresponding table, - Calculation of Gaussian and mean curvatures based on spline surface function. The method is applied to arterial geometries extracted from medical images with panceaticoduodenal arcade and ICA aneurysms. [1] A. Computational Generation of High Quality Quad Layouts

Leif Kobbelt*

*RWTH Aachen University

ABSTRACT

The conversion of raw geometric data (that typically comes in the form of unstructured triangle meshes) to high quality quad meshes is an important and challenging task. The complexity of the task results from the fact that quad mesh topologies are subject to global consistency requirements which cannot be dealt with by local constructions. This is why recent quad meshing techniques formulate the mesh generation process as a global optimization problem. By adding hard and soft constraints to this optimization, many desired properties such as structural simplicity, principal direction alignment, as well as injectivity can be guaranteed by construction. An even more challenging problem is the computation of quad layouts, where a coarse segmentation of the input surface into essentially rectangular patches is sought which also satisfies global consistency and shape quality requirements. While being structurally related, both problems need to be addressed by fundamentally different approaches. In my talk I will present some of these approaches and demonstrate that they can generate high quality quad meshes and quad layouts with a high degree of automation but that they also allow the user to interactively control the results by setting boundary conditions accordingly.

Instability Problems of Implicit FEM Solution Procedures for Fast Rotating Structures – Instability Sources and Solutions

Markus Kober*, Arnold Kühhorn**, Akin Keskin***

*Brandenburg University of Technology Cottbus - Senftenberg, **Brandenburg University of Technology Cottbus - Senftenberg, ***Rolls-Royce plc

ABSTRACT

For the solution of dynamic FEM problems in the time domain in general two possibilities exist. The first one is to solve the equations of motion with an explicit time-integration scheme, which has the advantage of being very fast but on the other hand the time-steps have to be very small for stability reasons. The second possibility is to use an implicit time-integration scheme in combination with a Newton or Quasi-Newton algorithm, which is computationally more expensive but allows for much bigger time-steps. It is well known that implicit solution procedures tend to become instable for the simulation of elastic rotating structures [1,2]. But if the simulation time of complex real-world structures is bigger than a few milliseconds explicit time-integration is too inefficient due to the small time-steps and an implicit time-integration scheme has to be used. We will demonstrate the appearance of instabilities during the implicit FE simulation of elastic rotating structures at the example of simple academic problems. If the time-step size is small enough to consider the boundary value problem to be linear in one time-step, stability maps for the time-integration algorithm can be computed [3]. Surprisingly, the described instabilities appear although the time-integration algorithm (e.g. Newmark scheme) is unconditionally stable with respect to the stability map. With the help of a simple elastic rotating pendulum we will derive the sources of the instabilities and discuss this problem in detail. It will be shown that the Newton algorithm for the solution of the nonlinear system of equations and especially the models stiffness and the used time-step size have a direct impact to the stability. These results are then transferred to the presented FE examples and a general solution for the described problems is presented. Finally, results of the transient implicit simulation of a realistic aero-engine model, rotating at 10.000 rpm and using the derived concept for stability, are shown. References [1] D. ***Otto-von-Guericke-Univerity Magdeburg

ABSTRACT

Already in an early stage of the design process the manufacturer has to be enabled to estimate the performance of new products. Thus, the design of the first draft can be favorably adjusted in order to reach specific goals. Furthermore, expensive prototypes are only required for the final testing. The aim of this contribution is to improve a previously developed holistic simulation approach for the evaluation of the acoustic behavior. Here, a combustion engine is used as an automotive example [1]. An experimental investigation on an engine test bench shows significant differences between the measured and predicted results in the area of the oil pan. These differences can be traced back to the oil, which leads to a frequency shift and smaller amplitudes. Until now the oil was only taken into account as an additional mass. To improve the results, a particle-based approach is coupled with the Finite Element Method (FEM). For this a higher order FEM code [2] and the open source Smoothed Particle Hydrodynamic (SPH) program SPHysics are used. Initially, a co-simulation is performed and validated with typical benchmark examples. The interface region coincides with the surface of the solid structure and features FE nodes as well as the first row of SPH boundary particles. The pressure of the fluid particles is applied to the FE structure as an external load, which causes a deformation of the solid and consequently leads to displacements and velocities of the boundary particles. The coupling nodes and particles do not need to be conformal, as the required displacement and velocity values can be computed at any point in the interface by means of the shape functions. In a last step, the proposed method for the acoustical simulation of an oil pan is validated based on a 2D academic benchmark test. The influence of the fluid in the oil pan is quantified by a transient simulation and an inspection of the frequency spectrum computed by Fourier transformation of the results. For future applications more sophisticated coupling techniques are implemented to further improve the quality of the numerical simulation. [1] F. Duvigneau, S. Nitzschke, E. Woschke, U. ABSTRACT

This work presents a concurrent multiscale method for thermomechanical properties of composite structures containing Phase Change Materials (PCM) particles at microscale. The PCM inclusions change from solid to liquid phase and lead to significant modifications of the macroscopic thermal behavior. The FE2 method [1] is extended to take into account phase change effects on the macroscale thermal heat conduction. For the mechanical behavior, a classical homogenization is performed on the same Representative Volume Element used in the FE2 procedure. The thermal behavior with phase change at microscale is strongly nonlinear and involves coupling with fluid flow in the liquid phase. An apparent heat capacity method proposed in [2] is used to model the thermal phase change in the inclusions. Thermal phase changes occur at almost constant temperature and the latent heat stored (or released) is largely higher than the energy exchanged by temperature variation. Thus, PCMs with phase change in range of room temperature have a great potential in building applications: improvement of thermal inertia of civil engineering constructions and reduction of energy consumption due to air conditioning. The method is applied to concrete including encapsulated paraffin wax. The results show that the macroscale temperature's fluctuations are smoothed as compared to concrete alone. In addition, the macroscopic temperature peaks are delayed in time. Furthermore, a comparison with a direct Finite Element analysis shows the ability of the proposed strategy to predict accurately the fully nonlinear thermal behavior of PCM based composites. Composite Crashworthiness Prediction for Bumper and Crush Can Assembly

Ravi Kodwani*, John Brink**, Rogerio Nakano***

*Mr., **Mr., ***Mr

ABSTRACT

The United States Automotive Materials Partnership (USAMP) approached Altair with the goal of predicting the automotive crash behavior of composite laminates subjected to 6 different test configurations. Coupon and generic component level test data were supplied to help with the development of material models. Material characterization process and determination of failure parameters using DOE are detailed in the presentation. Final correlation was to a series of “blind” sled tests completed on a woven ply composite bumper with SMC over-molded ribs and woven ply crush cans. Altair submitted the RADIOSS predictions to USAMP and USAMP shared the test data shared after that. Apart from this prediction, presentation also discusses delamination failure criteria using macro shell models and comparison with and without them.

ABSTRACT

System and parameter identification using methods of inverse analysis is a common problem in several engineering disciplines. In civil engineering applications the safety assessment of existing structures which often is the base for life-time predictions need system and parameter extimations for the investigated existing structures. Therefore inverse techniques are applied using sensor data from different physical fields, e.g. deformation data or temperature data. Usually only data from one physical field is used for the identifification of system parameters at one time. Therewith the interaction effects between different physical fields are usually not taken into account. As an example for this interaction effects the correlation between pores, damage and cracks driven by mechanical or temperature loading and the permeability of solids can be seen. Using data from deformation measurements and superimposing this data with measurements from the hydraulic head field leads to improved identification results for the material parameters and their distribution in the domain for both fields. Inverse analysis based on correlated multifield data allows a much more robust identification of essential system parameters. The paper will present an approach in which a thermo-mechanical-hydraulic analysis will be used for the material parameter identification in masonry dam structures, i.e. to identify regions of local damage in large scale structures. Uncertainty of measured data is taken into account and leads to an information about the probability distribution of the damnage zone. Issues such as correlation parameters and infuence of noisy measuremnet data will be discussed in the presentation. The presented approach has been applied for parameter identification of existing masonry dam structures in Germany, which are in operation for already 100 years.

ABSTRACT

Efficient model development for complex systems remains a challenge. Generating a mesh of sufficient quality for the Finite Element Method (FEM) can take months [1]. Research in agile design-to-simulation processes seeks to alleviate this bottleneck by taking on the difficult task of pairing automatic discretization techniques with numerical methods that are capable of producing satisfactory results. In this work, we present the Conforming Reproducing Kernel (CRK) numerical method. In this new approach, approximation functions are constructed using the reproducing kernel method with kernel functions created using Bernstein-Bezier splines on local geometry subdivisions. Meshfree methods, such as the Reproducing Kernel Particle Method (RKPM) [2], have an advantage over FEM as a high-quality mesh is not required. However, this flexibility in the construction of shape functions does present new challenges. Domain integration must be reformulated in order to maintain high accuracy and efficiency [3]. Concave geometries require special consideration so concavities are preserved. Material interfaces call for special attention so that weak discontinuities can be captured. Unlike traditional meshfree methods, CRK uses subdivisions to guide the construction of approximation functions. This allows CRK to better represent domain boundaries, especially nonconvex geometries. Also, the underlying reproducing kernel method gives CRK the flexibility to blend approximations over low quality subdivisions or handle non-contiguous meshes, making it compatible with automatic discretization processes that produce may produce low quality meshes. Previous work focused on developing the concept in two dimensions using C^1 splines on triangulations. In this presentation, the method is extended to three dimensions and kernels are constructed using tetrahedral subdivisions. Examples utilizing the conforming kernels are shown and results are compared to predictions using FEM and RKPM. [1] M. Hardwick, R. Clay, P. Boggs, E. Walsh, A. Larzelere and A. Modification of Response Surface Single Loop Method in Reliability-Based Optimization

Nozomu Kogiso*, Hiroaki Tanaka**

*Osaka Prefecture University, **Osaka Prefecture University

ABSTRACT

This study proposes an improvement method of the response surface single loop method (RSSL) [1] for the reliability-based optimization. The RSSL achieves computational efficiency with high approximation accuracy by directly evaluating the failure probability using the Hermite polynomial and the second-order approximated limit state function. Since the method does not require the most probable point (MPP) searching, the single loop reliability-based optimization is achieved, once the second-order approximation of the limit state function is established. However, we found from our experiment of application to several example problems that the RSSL method does not always have a sufficient accuracy. Especially when the approximation point of the limit state function is apart from the MPP, the approximate accuracy is deteriorated. While, the accuracy is sufficient, if the approximation point is closed to the MPP. For the purpose, we introduce an approximation point updating process in the optimization loop that utlizes an idea of the Single Loop Single Vector (SLSV) method [2] and the modified SLSV method [3]. It means that the second-order approximation point of the limit state function is updated to the approximated MPP by the SLSV method in each optimization step. Since the RSSL does not require the MPP to evaluate the failure probability, the failure probability approximation accuracy is sufficient for roughly approximated MPP. Through several numerical examples, the validity of the proposed method is illustrated by comparing between the proposed method, the orignal RSSL and also the SLSV. [Reference] 1. R. Mansour and M. Characteristics of Singular Electric Displacement Fields at the Vertex of Interface in Piezoelectric Joints

Hideo Koguchi*, Hiromi Sato**

*Niigata Institute of Technology, **Tsugami Corporation

ABSTRACT

Singular fields of stress and electric displacement occur at the vertex of interface in piezoelectric joints under an external loading and the input of voltage1). Until now, singular stress fields are intensively investigated for relating to the reliability of joints. It can be expected that concentrated electric displacements causes large electric fields in an adjacent space (air) and electric potential will be induced on the surface of electrode when the electrode approaches to the electric field. In the present paper, a piezoelectric joint which four blocks of piezoelectric material are bonded using an insulated resin is analyzed. In this joint, singular fields occur around a center gathering four vertexes in blocks and the intensity of singularity in electric displacements around the center of cross section in the joint may be four times larger. The intensity of singularity in electric displacements is numerically investigated using a conservative integral method to pursue the possibility of application of the singular fields. It is shown that when piezoelectric materials with large piezoelectric constant are used, electric displacements are amplified. Electric fields in air near the vertex of interface have also a singularity. In this study, a singular field of electricity in air is investigated using a commercial finite element program. The order of singularity in air is a little bit different from that in the joints. The influence of thickness of resin on the electric field in air is investigated. When the thickness of the resin increases, the intensity of singularity also increases. However, when the resin becomes thick, the singular fields do not influence on electric fields at the center region of cross section in the joint. Hence, a suitable thickness of the resin exists for amplifying the electric field in air. Next, a generated voltage in the joints and in a single phase piezoelectric material for loading on the side surface is investigated in experiment. Voltage in the joints is 1.5 times as large as that in the single phase material. It is supposed that this is attributed to the singular fields in electric displacement. Reference 1) H. Koguchi, H. ABSTRACT

Electron beam melting (EBM) is a powder bed fusion (PBF) -type additive manufacturing (AM) process using electron beam (EB) as power source for fusing metal powder particle to fabricate metal parts. The most characteristic aspects of EBM process, compared with other metal AM process, such as selective laser melting (SLM) laser beam-PBF, are the high beam power and high scanning speed of electron beam (EB) These characteristics are believed to be beneficial for controlling the solidification condition and resultant microstructure with a large degree of freedom since they allow us to control temperature distribution variously. In this study, multi pass EB scanning process under various process conditions have been investigated by finite element method (FEM) using surface Gaussian heat source. Temperature gradient (G) and solidification rate (R) were calculated from the temporal change of simulated temperature distribution, and they were plotted on solidification map to predict microstructure. The predicted microstructures were compared to the experimentally observed microstructure to examine the validity of the scheme for predicting the microstructure of EBM-built parts. Simulated melt pool size is consistent with experimental results. With increasing heat input, predicted microstructures change from columnar to equiaxed grains. The columnar-to-equiaxed transition (CET) established for casting process is not applicable for EBM process. Peak temperature increases as pass number increases, and it will be kept constant after several passes. Melt pool width and depth increased at first and then reach stable status. Finally, a large melt pool of trapezoidal shape forms. Temperature gradient, solidification rate and cooling rate all decrease with increasing pass number. This suggests that the high scanning speed of EB can be utilized to control solidification condition precisely by controlling the local temperature gradient and solidification dynamically to obtain desired properties.

ABSTRACT

An explicit time integration scheme for finite element solution of contact-impact problems with stabilization of contact forces using a bi-penalty formulation in finite element method for one dimensional case is presented [1]. The penalty approach for enforcing of contact constraints can be applied not only to the stiffness term but also to the inertia of the contact boundary condition. This technique is known as the bipenalty method [2]. By means of adding the bi-penalty terms (additional mass and stiffness terms concurrently) into the equations of motion corresponding to the contact pairs, we obtain a modified local dynamic system. In principle, we attune a frequency character of these equations of motion corresponding to the nodes for which contact conditions apply. The stability limit for an un-penalized/contact-free system is preserved by a special choice of mass and stiffness penalty parameter ratio. For time integration, the explicit time integration scheme is based on splitting of bulk and contact accelerations [3]. Dynamic situation in a bar without respecting contact forces is computed by pull-back time integration [4] with the critical time step size. Moreover, the time stepping process produces stable results for a large range of the stiffness penalty parameter. Behavior of the presented method is shown on impact problems of heterogeneous bars. The special attention is paid to study spurious oscillations of contact forces in one-dimensional contact-impact problem of bars. ABSTRACT

The Mg-Ca binary alloys microalloyed with Al and Zn show precipitation hardening by aging because plate-like precipitates (or Guinier-Preston zones) are formed on the (0001) plane (basal plane). Furthermore, an indium addition is effective for enhancing age hardening behavior because it changes the habit plane of precipitates from the basal plane to {01-10} or {2-1-10} planes (prismatic planes) [1]. Fundamental knowledge on the formation process of precipitates and the relationship between the microstructure and mechanical properties is essential for microstructure design of Mg-based alloys. In this study, the formation process of plate-like precipitates on the basal plane is simulated by three-dimensional (3D) phase field simulations, where the elastic strain energy derived from the precipitation is explicitly considered based on the phase-field microelasticity theory. It has been simulated that the volume fraction of precipitates increases with time while the number density of precipitates decreases with time. Furthermore, by using the simulated 3D two-phase microstructure, the motion of a dislocation on the (0001) slip plane is simulated under an external shear stress in order to elucidate the influence of precipitates on the dislocation dynamics. Simulation results show that the existence of precipitates delays the dislocation motion even if the dislocation does not encounter any precipitates. It has been found that the dislocation motion is influenced by the elastic interaction between the dislocation and precipitates. The dislocation dynamics simulations are performed with varying the magnitude of external shear stress and the value of critical resolved shear stress (CRSS) is estimated. It has been simulated that during the aging process, the value of CRSS increases with time in the initial stage of precipitation while the value of CRSS decreases with time in the later stage of precipitation. The simulated change in the CRSS value with time is assumed to correspond to the precipitation hardening curve. It has been shown that plate-like precipitates on the basal plane are effective for precipitation hardening, and the elastic interaction between a dislocation and precipitates has a great influence on the mechanical properties of magnesium alloys. Effects of Turbulence on Ignition of Fully Premixed Mixtures with Hydrocarbon Fuels

Takahiro Konagamitsu*, Masayasu Shimura**, Yuki Minamoto***, Mamoru Tanahashi****

*Tokyo Institute of Technology, **Tokyo Institute of Technology, ***Tokyo Institute of Technology, ****Tokyo Institute of Technology

ABSTRACT

In order to realize a highly efficient spark ignition engine, establishment of combustion technology using low equivalent ratio, high turbulence intensity, high exhaust recirculation rate and the like is required. Under such conditions of combustion, however, ignition is difficult and the ignition characteristics are unknown, so it is necessary to clarify ignition characteristics such as the ignition criteria and ignition delay time. In this study, to determine the ignition criteria and effects of turbulence on the localized ignition delay time, direct numerical simulations (DNS) of forced ignition of lean fully premixed mixtures have been performed for hydrocarbon fuels such as methane and n-heptane with a high exhaust gas recirculation rate at high pressure. In the present DNS, the domain is initially filled with a fully premixed mixture at a uniform preheated temperature. As combustion conditions, equivalence ratio of the mixture, initial pressure, initial exhaust gas recirculation rate and uniform preheated temperature are set to be 0.5, 1.0 MPa, 20 % and 700 K for all fuels cases. A high-temperature kernel is used as an initial ignition kernel, and one-dimensional DNS are preliminary performed to determine the ignition criteria in terms of the ignition source energy and the thermal conduction from the ignition kernel during the induction period. Subsequently, two-dimensional DNS are performed with an initial kernel size and temperature which yields successful ignition for the one-dimensional laminar cases, to clarify the influence of the turbulent strain rate on the ignition delay time. It is found that the turbulent strain rate in the high-temperature region influences the ignition delay time. The ignition delay time increases proportionally to the square of strain rate averaged in the high concentration region of intermediate species during the induction period. This suggests that the ignition in a turbulent field is based on the balance between the influence of the local strain rate in the preheating region and the chemical time scale. Based on these observations, a simple relationship for the ignition delay time was considered based on the mean strain rate in the high concentration region of intermediate species during the induction period. The local ignition delay times predicted by this relationship, normalized using a corresponding laminar flame speed, flame thermal thickness and laminar ignition delay time, yields similar ignition trends for different fuels considered.

Gas-liquid Two-phase Flow Calculation Using Moving Particle Full-Implicit (MPFI) Method

Masahiro Kondo*

*University of Tokyo

ABSTRACT

Gas-liquid two phase flow emerges in various industrial processes like boiling, mixing, washing, bubble behavior and so on. To calculate gas-liquid two phase flow, numerical stability is very important because the large density ratio of the two fluid may easily result in instability. It is also the case in particle methods, and emperical relaxations were taken to avoid instability such as such as particle scattering. To achive the numerical stability, MPFI (Moving Particle Full-Implicit) method took the approach based on the analytical mechanics, where the monotonic decrease of mechanical energy is assured. Therefore it is thought that the instability like particle scattering does not occur even in a gas-liquid system. In this study, gas-liquid two phase calculations are tested using the MPFI method to check the ability to run the calculations stably.

A Numeric Algorithm for Solving Kinetic Equations Across All Flow Regimes

Bo Kong*, Rodney Fox**

*Ames Lab-USDOE, **Department of Biological and Chemical Engineering , Iowa State University

ABSTRACT

In nature and many engineering applications, the particle volume fraction in fluid-particle flows often exhibits large variations. In other words, the particles can be closely packed in some locations, and very dilute in other locations at the same time, such as in circulating fluidized bed reactors. Traditionally, a hydrodynamic description of particle phase is often used to simulate fluid-particle flows, which has been shown to be inaccurate for dilute flow regions when particle-particle collisions are infrequent. On the other hand, quadrature-based moment methods (QBMM), which use Gauss quadrature to approximate particle velocity distribution, have been shown to be able to provide accurate solutions for the kinetic equation. However, in dense regions, the explicit nature of QBMM makes it highly inefficient compared to hydrodynamic solvers, in which the implicit methods can be used for spatial fluxes. To accurately simulate all fluid-particle flow regions, a novel algorithm, based on splitting the kinetic flux dynamically and locally in the flow, is proposed in this work. In it, a traditional hydrodynamic solver is employed in the dense region, while in dilute to very dilute regions a kinetic-based finite-volume QBMM solver is used. This algorithm was implemented in OpenFOAM, an open-source CFD package, for particle velocity moments up to second order. Three different flow conditions, fluidized bed, wall-bound channel flow, and homogeneous cluster-induced turbulence flow, are used to test the accuracy and robustness of the proposed flux-splitting algorithm. By varying the average particle volume fraction in the flow domain, it is demonstrated that this algorithm can handle seamlessly all flow regimes present in any particular application. In this talk, we will also briefly introduce a new algorithm for simulating polydispersed dense particle flows based on QBMM.

Structural Optimization for Mechanical Structure under Linear and Nonlinear Geometry by Using Topological Technique

Suphanut Kongwat*, Hiroshi Hasegawa**

*Shibauara Institute of Technology, Japan, **Shibauara Institute of Technology, Japan

ABSTRACT

Structural optimization is a one technique to determine an optimal value which becomes a powerful technique for engineering design problem. There are three main types of structural optimization methods i.e. size optimization, shape optimization and topology optimization. According to the best outcome, the topology optimization is considered as a complex method. This is because the optimal size and shape of the initial layout are not taken into consideration. Almost of topology optimization problems are concerned to linear behavior of material by assuming a small displacement for structure. However, when the external load is applied to the structure and causes large deformation, this case is necessary to consider the problem into nonlinearity. The nonlinearities of mechanical structure are related to three main types of problem include behavior of the material, geometry and contact and friction. So, the aim of this research is to investigate the difference of optimal layout between linear and nonlinear material geometry for mechanical structure by employing the topology optimization method. For performing an optimization problem, pre-processing and post-processing of the finite element method (FEM) are required to support the optimization processes. The problem is defined into the simple mechanical structure which created in three-dimensional model (3D) by Salome-Meca. A topology optimization is formulated based on Simplified Isotropic Material with Penalization method (SIMP). The objective for optimization process is to minimize the compliance of structure by corresponding to volume fraction constraint. As the Salome-Meca is open source software, user has to write python script for any problem which is more complicated than the common feature of this software. Absolutely, the optimization process is more complicated than the common feature of Salome-Meca, all of optimization algorithm has to be written with python script by user and combine to the software for computation process. For linear optimization, this is a simple computation by requiring material properties into elasticity, boundary conditions and optimization algorithm. The optimization under nonlinear geometry is more complex than linear optimization by requiring stress-strain relation in plasticity. Moreover, time-step control is also required under nonlinear optimization to control a convergence of results. Finally, the optimal layout of optimization process under linear and nonlinear conditions is obtained and the comparison results of the optimal shape between two cases are completely different. So, the effect of nonlinearities should be concerned into optimization process for suitable results of nonlinear problem.

A Recursive Multilevel Trust Region Method for Phase-field Models of Fracture

Alena Kopanicakova*, Rolf Krause**

*Università della Svizzera italiana, **Università della Svizzera italiana

ABSTRACT

A state of the art strategy for predicting crack propagation, nucleation and interaction is the phase-field approach. In this approach a damage variable is introduced, which characterizes the state of the material between the unbroken and the broken state. However, phase-field methods require the solution of strongly nonlinear coupled systems of equations at each time-step. This is computationally challenging due to huge number of unknowns and the ill conditioning caused by local changes in the damage variable. As a consequence, the design of efficient solution methods becomes an important task. Two popular solution strategies are monolithic and staggered schemes. In the monolithic approach a fully-coupled non-linear system is solved in each loading step/ time-step, whereas in the staggered approach the evolution operator is split algorithmically into the phase field and the displacement field. Then, in each time step, it is successively solved for both quantities. Numerical evidence shows that the staggered approach is more robust than the monolithic one, but it often underestimates the speed of the crack evolution. For this reason, small time-steps are usually required. On the other hand, the monolithic approach allows for bigger time-steps, but it results in highly ill-conditioned coupled system of equations to be solved. In this work, we employ a recursive multilevel trust region (RMTR) algorithm for the monolithic approach. The method tackles the nonlinearity directly on each level. This is done by introducing level dependent nonlinear objective functions, whose minimization can yield good coarse level corrections for the fine level problem. In contrast to the standard approaches, our approach makes use of both the monolithic and the operator splitting approach. On the fine level, the RMTR solution strategy operates directly on the coupled systems of equations. On the coarse levels, the models are built by using operator splitting techniques. The numerical examples will show that presented optimization technique leads to highly efficient solution strategy. The efficiency will be demonstrated by analyzing convergence behaviour and performing comparison to the commonly used nonlinear solvers.

A Fully Compressible Multiphase SPH Scheme for Hypervelocity Impacts

Barry Koren*, Iason Zisis**, Bas van der Linden***

*Eindhoven University of Technology, The Netherlands, **Praxis Software, Greece, ***LIME B.V, The Netherlands

ABSTRACT

In Smoothed Particle Hydrodynamics (SPH) for weakly compressible flows, particles of unequal masses are typically employed. In this approach, the mass ratio of the particles determines the density ratio of the different phases. For fully compressible flows, particles of equal masses are advised [1], where the smoothing length needs to adapt to large variations in density. Here, the ratio of initial densities dictates the discretization length per phase, which implies computational and geometrical restrictions [2,3]. Schemes based on number-density can accommodate particles of unequal masses and can offer a robust alternative. The present study presents and validates a number-density SPH scheme, using particles of unequal masses. Test cases considered are: (i) a one-dimensional gas-liquid shock-tube problem with known analytical solution, (ii) two classical two-phase shock-bubble-interaction experiments, and (iii) an aluminum-lead hypervelocity impact experiment, in which the aluminum and lead objects are subjected to plastic deformation, liquefaction and even sublimation. It is found that the above scheme can accurately simulate the propagation of shocks and yields improved results in the simulation of hypervelocity impacts of solids. 1. D.J. Price. Higher Order Total Variation for Regularizing Partial Differential Equations

Adeline Kornelus*, Rodrigo Platte**

*Arizona State University, **Arizona State University

ABSTRACT

One of the main difficulties in solving the incompressible Navier-Stokes equations in fluid dynamics is the transfer of kinetic energy from coarse spatial scale to finer spatial scale, resulting in finite time singularities in the solution. In Fourier analysis, this phenomenon is described by the energy cascade from low modes to high modes. When these equations are discretized, the energy in high modes are usually lost, and as a result, spurious oscillations appear near discontinuities. In this talk, we propose using regularization techniques such as higher order total variation (HOTV), often used in image processing, to improve the numerical solution of such problems. We illustrate the accuracy of the proposed schemes using Burgers' and Euler's equations. The main idea is to penalize spurious oscillations using the polynomial annihilation and L1 minimization techniques. We treat the partial differential equation residual as the fidelity term. In particular, we show these regularized methods lead to better stability and accuracy. We apply HOTV regularization to numerical methods such as Fourier, Finite Differences and Discontinuous Galerkin. We observe that regularization properties of the solution on large scale and small scale depend on the numerical method used to discretize the equations. We also show how different number of elements and/or order of the method affects the quality of the solution. Finally, comparisons with other smoothing techniques such as entropy viscosity and essentially non-oscillatory methods are also provided.

Fluid-Structure Interaction Framework for Compressible and Incompressible Flows: Application to Aerospace and Marine Engineering

Artem Korobenko*

*University of Calgary

ABSTRACT

A Fluid-Structure Interaction (FSI) framework for compressible and incompressible flows is presented. The framework is composed of stabilized methods for fluid mechanics and thin-shell structural mechanics formulation. The key constituents of the framework are presented, including the coupling strategies, in a context of various aerospace and marine engineering applications.

ABSTRACT

Key words: Additive manufacturing, CT Scans, Numerical homogenization, Window method Recent developments in additive manufacturing have provided a unique possibility to create complex structures with porosity on micro- and meso-structural levels. Such designs can outperform conventional materials in specific industrial applications, e.g. turbine blades with a transpiration cooling. However, the high flexibility of the input parameters for the 3D printers, such as the laser diameter, hatch distance etc., challenges a reliable estimation of the mechanical behavior of the final parts. Moreover, a high variation of porosity in all of the material directions limits the application of analytical bounds based on the void fraction ratio. Numerical homogenization is an efficient and robust alternative to perform a non-destructive evaluation of the material characteristics based on high-resolution 3D images of produced specimens. The conventional Finite Element Method applied to numerical homogenization leads to a labor-intensive meshing procedure to extract the representative volume elements that makes it impractical from the industrial point of view. Furthermore, non-symmetric micro-architectured structures make it difficult to apply correct boundary conditions for the solution of the microstructural boundary value problem. To address these issues, in the scope of the presented work the Finite Cell Method [1] is employed in combination with the window method [2],[3]. A road map is presented for the automatized numerical computation of the homogenized elasticity tensor of additively manufactured steel structures using 3D images. The computational results are verified with the direct finite cell computation of a given produced specimen. Validation of the proposed model is performed comparing the numerical results with the results stemming from experimental tests. REFERENCES [1] Düster, A., Parvizian, J., Yang, Z. and Rank, E. Solution of PDE Constrained Inverse Problems from a Machine Learning Perspective

Maximilian Koschade*, Phaedon-Stelios Koutsourelakis**

*Technical University of Munich, **Technical University of Munich

ABSTRACT

The increasing interest in probabilistic methods for uncertainty quantification as well as PDE constrained problems typically relies on deterministic black-box solvers embedded within iterative algorithms such as Markov Chain Monte Carlo. While enabling the utilization of well-established and capable algorithms such as for instance the Finite Element Method, this approach obscures the underlying physical laws and state variables from the machinery of probabilistic inference. We advocate for an intrusive, fully probabilistic approach which constructs a probability distribution over all state variables of the PDE, which are constrained or mutually entangled by underlying physical laws. As such this method foregoes the explicit solution of the forward-model in a conventional sense and yields what can be considered a probabilistic white-box model, where forward solution and probabilistic inference no longer exist as decoupled entities. We demonstrate the applicability of this approach for the adjoint-free solution of a nonlinear, elliptic PDE constrained inverse problem, where we exploit the cheap availability of curvature information inherited from the Finite Element Method to conduct second order inference on our joint posterior over all state variables and unknown quantities simultaneously.

Condition Assessment and Prognosis in Fluid-Structure Interaction through a Data-Driven Proxy Model Inversion Framework

Justyna Kosianka*, Christopher Earls**

*Cornell University, **Cornell University

ABSTRACT

It is essential to identify damage within a structure as early as possible in order to propose corrective measures to prevent mechanical failure – ultimately extending service life. Such damage detection can be effected through non-destructive means that employ the updating of a physics model describing the system of interest. The resulting inverse problem is concerned with locating and characterizing the damage, by considering the structural dynamic response, before and after the onset of damage. Such model-based approaches also afford prognosis potential; as a calibrated physics model is subsequently available for the damaged system. In this work, a partitioned fluid-structure forward modeling capability is developed from combining an open source CFD tool (OpenFOAM) with an open source CSD solver (CU-BEN) in a tightly coupled framework that affords stable solutions. However, such high fidelity, coupled-physics forward modeling is prohibitive for use in solving model-based inverse problems, where the forward model must be called repeatedly; thus necessitating the consideration of reduced-order modeling methods. Within the context of inversion, the high-fidelity FSI forward model is evaluated on a series of plausible (physically inspired) “damaged” states to create an offline library of modeled damaged responses. These responses are expressed in compressed form through proper orthogonal bases (e.g. obtained via proper orthogonal decomposition) and subsequently represented as points on a certain Riemannian manifold. From this off-line library of compressed response representations from the FSI model, a proxy model is constructed, by “manifold interpolation,” on the nonlinear Riemannian manifold to “fill in the gaps” for damage contexts not explicitly contained within the library, but required as part of the inversion. This subsequent online inversion is effected as a non-convex optimization problem, employing a genetic algorithm to arrive at a plausible reduced order modeling instance that conforms to observations within some prescribed limits. An exploration of spatial decomposition methods (e.g. POD vs DMD) and data sampling schemes is presented for a simple test problem of an elastic cantilever oscillating in a bluff body flow with simulated erosion damage. The framework is scaled up for use on a marine structural element, such as propellers and basic ship hull components.

Dynamic Failure of High Energy Materials

Marisol Koslowski*, Nicolo Grilli**, Camilo Duarte Cordon***

*Purdue University, **Purdue University, ***Purdue University

ABSTRACT

Polymer bonded explosives consist of high energy particles in a polymeric binder. When these composites are subjected to heat, impact, or other stimulus they undergo a rapid chemical change. The sensitivity to initiation depends on the amount of energy available in the system and on the rate at which it is released. This process is controlled by the formation of high temperature localized regions known as “hot spots”. The mechanisms of hot spot nucleation are controlled by the microstructure, for example in the same sample some particles ignite while others do not. Finite element simulations that explicitly describe particles, are performed to study the sensitivity of the microstructure to initiation and to identify the mechanisms of hot spot formation under a range of mechanical stimulus. The finite element model incorporates plasticity, fracture and heat transport using a phase field approach. Different microstructures with initial defects, including cracks, debonding and voids are analyzed. Our work suggests that heat generated by friction at preexisting microcracks and at particle binder interfaces are of key importance for hot-spot formation.

ABSTRACT

This study presents a framework to evaluate the spatial correlation of tsunami risks among multiple coastal cities. The proposed framework consists of the three processes. First, response surfaces of the tsunami heights at selected multiple coastal cities are obtained from a series of numerical simulations in consideration of conceivable uncertainties of a tsunami hazard. Here, highly developed numerical simulations are extensively and efficiently utilized to obtain reliable data of tsunami heights under a certain scenario. Second, the statistical data sets of the tsunami height are calculated from the obtained response surfaces with the help of the Monte-Carlo simulation (MCS) [1]. Here, the use of the response surfaces, which are regarded as surrogate models, allows us to significantly reduce the calculation costs, as well as to study tendencies of simulated results against input parameters and calculation conditions [2]. In this procedure, a probability density distribution of the tsunami height is also analyzed to characterize the variability in each city. Third, the principal component analysis (PCA) is performed using the covariance matrix that can be obtained from the results of the MCS. Finally, the low risk correlation of the tsunami heights among the selected coastal cities is analyzed based on the result of PCA. Selecting the 2011 off the Pacific coast of Tohoku Earthquake as a target scenario for our tsunami risk evaluation, we present a numerical example to assess the appropriateness of the suggested framework. In specific variabilities of a few fault parameters are considered in this numerical example, and the modeling error of the numerical scheme is also considered as one of the uncertainties. Response surfaces of the coastal cities in Tohoku area are obtained from the results of several sets of tsunami simulations, then spatial correlation among the cities is analyzed. Based on the obtained results, the effectiveness and potential in providing against forthcoming tsunami hazards are discussed, and a characteristic of tsunami risk in Tohoku area is also mentioned. A Nitsche Based Extended Finite Element (XFEM) Approach to Embedded Contact Interfaces

Hardik Kothari*, Rolf Krause**

*Università della Svizzera italiana, **Università della Svizzera italiana

ABSTRACT

Interface problems occur in many applications in physics. For these problems, it is important to capture discontinuous behavior in order to obtain a good approximation. The extended finite element method (XFEM) allows us to model the evolution of an interface without remeshing as the interface evolves. The XFEM approach captures the discontinuities along interfaces by enriching the standard finite element solution space. The interfaces are represented, implicitly in this case, using Heaviside functions. In the case of fracture mechanics, after the initial crack propagation the newly created surfaces could also come in contact, which would give rise to self contact. The XFEM framework is well suited to model interfaces, but it becomes complicated to model contact interfaces. This is due to the fact that the contact boundaries are not explicitly represented by the nodes or the element edges. In this work, we employ Nitsche's method to weakly compute the contact constraints over these implicit interfaces. Thus, we present a unified framework for fracture and contact mechanics problems, where crack propagations and contact problems are solved on the same mesh. As a crack propagates through the mesh, it is quite likely that the newly created crack passes very close to the nodes or the element edges. Due to this, some elements are fragmented into very small and into very large fractions, which gives rise to a highly ill-conditioned linear sys- tem. Such ill-conditioned systems require special solvers and preconditioners. In our work we present a variation of a multigrid method, known as a semigeometric multigrid as a technique to reduce computational complexity. This method uses pseudo-L2 projection based prolongation and restriction operators to transfer the information between the non-nested mesh hierarchies. We demonstrate the robustness and the efficiency of this method as a solver and as a preconditioner in a series of numerical examples. [1] R. Becker, P. Hansbo and R. Stenberg. Stochastic Response Determination of Nonlinear Systems with Singular Diffusion Matrices via a Wiener Path Integral Based Technique

Ioannis A. Kougioumtzoglou*, Apostolos F. Psaros**, Ioannis Petromichelakis***

*Columbia University, **Columbia University, ***Columbia University

ABSTRACT

In many random vibration problems including stochastically excited multi-degree-of-freedom (MDOF) systems subjected to forces applied to only few of the DOFs, as well as a certain class of coupled electro-mechanical energy harvesters, the solution of a system of Stochastic Differential Equations (SDEs) involving singular diffusion matrices is required. This problem can be viewed, alternatively, as a set of SDEs, in conjunction with a set of homogeneous ODEs. In the present work, the Wiener Path Integral (WPI) technique, developed in \cite{koug2} to treat systems with non-singular diffusion matrices, is extended to account for coupled SDEs with singular diffusion matrices. Specifically, the WPI technique determines the response transition PDF of a system of SDEs, based on a variational argument and the solution of the corresponding variational problem. For the herein considered problem, the set of homogeneous ODEs is identified as a set of constraints imposed on the response of the SDEs; thus, leading to a constrained variational problem. Next, relying on \textit{Calculus of Variations} tools, two distinct solution methodologies are proposed. The first, more general one, treats the constraints by utilizing the Lagrange multiplier technique, while the second, which is limited to problems where the set of ODEs forms a linear system (linear constraints), takes advantage of the direct Ritz method and the properties of the nullspace of the constraint matrix, similarly to \cite{antoniou2017}. In this manner, the constrained variational problem is reduced to an unconstrained optimization problem. It is noted that the proposed framework can readily account for additional, physically imposed constraints as well, and thus, address constrained dynamics problems also. The versatility of the technique is demonstrated through diverse numerical examples, while its accuracy is validated by comparisons with pertinent Monte Carlo simulation (MCS) data.

Collapse Resilience of Reinforced Masonry Structures Under Seismic Loads

Andreas Koutras*, P. Benson Shing**

*University of California San Diego, **University of California San Diego

ABSTRACT

Reinforced masonry is widely used for low-rise construction in North America, including regions of high seismicity. Under extreme seismic forces, reinforced masonry buildings designed to comply with current codes are expected to have a low probability of collapse. Nevertheless, prior studies using simplified analytical models have shown that low-rise short-period buildings, including those constructed of reinforced masonry might not meet this expectation of the codes. This could be largely attributed to the overly conservative simplified models that were used for such analyses. To provide a more realistic assessment of the collapse potential, this paper presents a refined finite-element analysis scheme to model the inelastic behavior of reinforced masonry structures. In this scheme, smeared-crack shell elements are combined with cohesive discrete crack interface elements to model the compressive crushing and tensile fracture of masonry. The cohesive interface elements allow for a more precise representation of crack opening and closing as well as shear sliding across cracks. Reinforcing bars are modeled with beam elements that have geometric and material nonlinearities to capture bar buckling and fracture. The bar elements are connected to the masonry elements through interface elements to represent the bond-slip and dowel-action behaviors. To enhance the robustness and accuracy of the numerical solution, an element removal scheme is introduced so that the weakly restrained nodes and associated elements resulting from bar fracture or masonry crushing are removed. The material models and the interface elements have been implemented in the commercial software LS-DYNA. The modeling scheme is validated with data from quasi-static cyclic tests performed on flexure- and shear-dominated reinforced masonry walls, as well as with results of shake-table tests of reinforced masonry building systems with earthquake ground motions. Furthermore, the modeling scheme is applied to the time-history analyses of several reinforced masonry building archetypes that have been designed according to current code provisions. The buildings are subjected to bi-directional base excitation to evaluate their seismic performance through collapse.

Physics-constrained, Data-driven Discovery of Coarse-grained Dynamics

Phaedon-Stelios Koutsourelakis*, Lukas Felsberger**

*Technical University of Munich, **Technical University of Munich

ABSTRACT

This paper is concerned with the discovery of data-driven, dynamic, stochastic coarse-grained models from fine-scale simulations with a view of advancing multiscale modeling. Many problems in science and engineering are modeled by high-dimensional systems of deterministic or stochastic, (non)linear, microscopic evolution laws (e.g ODEs). Their solution is generally dominated by the smaller time scales involved even though the outputs of interest might pertain to time scales that are greater by several orders of magnitude. The combination of high-dimensionality and disparity of time scales has motivated the development of coarse-grained (CG) formulations. These aim at constructing a much lower-dimensional model that is practical to integrate in time and can adequately predict the outputs of interest over the time scales of interest. The Mori-Zwanzig (MZ) formalism provides a rigorous mathematical foundation for constructing such an effective model. Apart from the largely unsolved computational challenges associated with finding the terms in the Generalized Langevin Equation (GLE) prescribed by MZ, it does not address the issue of finding a good set of CG state variables. Furthermore, even if the evolution equations for the variables selected were perfectly known, it is difficult (without additional assumptions such as the prescription of a lifting operator) to reconstruct or infer the evolution of the full, fine-scale system. Hence if the observables one is interested in predicting, do not exclusively depend on the coarse variables selected, the CG model constructed is not useful. In this paper, we treat the CG process with a probabilistic state-space model where the transition law dictates the evolution of the CG state variables and the emission law the coarse-to-fine map. The directed probabilistic graphical model implied, suggests that given values for the FG variables, probabilistic inference tools must be employed to identify the corresponding values for the CG states and to that end, we employ Stochastic Variational Inference. Naturally, one of the most critical questions pertains to the form of the CG evolution law which poses a formidable model selection issue. We advocate a sparse Bayesian learning perspective based on Automatic Relevance Determination (ARD) which induces sparsity in the solutions identified, avoids overfitting and reveals qualitative features of the CG evolution The formulation advocated enables the quantification of a crucial, and often neglected, component in the CG process, i.e. the predictive uncertainty due to information loss that unavoidably takes place and manifests itself in uncertainty in the predictions.

Multi-scale Modelling of Linear and Non-linear Locally Resonant Metamaterials

Varvara Kouznetsova*, Ashwin Sridhar**, Priscilla Silva***, Tim van Nuland****, Marc Geers*****

*Eindhoven University of Technology, **Eindhoven University of Technology, ***Eindhoven University of Technology, ****Eindhoven University of Technology, *****Eindhoven University of Technology

ABSTRACT

Locally resonant metamaterials are a relatively new class of metamaterials targeting manipulation of acoustic (and more generally mechanical) waves at subwavelength frequencies. The microstructure of these metamaterials is specifically designed to provoke interaction between propagating mechanical waves and fine scale micro-inertia mechanisms, leading to exotic emerging phenomena, such as band gaps, i.e. frequency ranges in which waves do not propagate or highly attenuated, negative refraction index etc. Pushing the material behavior into a non-linear regime opens even more possible applications, e.g. tunable waveguides, adaptive passive vibration control, superdamping, acoustic diodes, cloaking, noise insulation and (vibro-acoustic) energy harvesting. The development and design of such materials and devices made thereof, requires advanced modelling techniques, capable, on one hand, to deal with complex geometries, boundary conditions and excitations, and on the other hand be computationally more efficient than direct numerical simulations. In this work, a novel computational homogenization approach will be presented for multi-scale modelling of locally resonant materials. Originating from the classical computational homogenization technique, well established for quasi-static problems, an extension to transient problems has recently been developed [1]. For linear problems, the static-dynamic decomposition can be used to derive the closed form homogenized equations representing an enriched micromorphic continuum, in which additional kinematic degrees of freedom emerge to account for micro-inertia effects [2]. In non-linear case, fully coupled two scale transient computational homogenization is used to study the wave dispersion in finite size macroscopic structures, demonstrating various phenomena emerging due to the presence of non-linearities , e.g. amplitude dependent attenuation response and higher-order harmonics generation. A new design of a vibro-diode, allowing wave propagation in one direction only, has been proposed based on the combination of the linear and non-linear local resonators. Microstructure-Property Analysis Accelerated by Machine Learning Technique with Phase-field Method and Image-based Property Calculations

Toshiyuki Koyama*, Yuhki Tsukada**

*Nagoya University, **Nagoya University

ABSTRACT

Recently, the phase-field (PF) method has been becoming the de facto standard simulation method for calculating various types of phase transformations and microstructure developments in real materials. Since the inhomogeneous microstructure data are available from the simulation, the materials properties are estimated based on the image-based calculation in which the inhomogeneous microstructure data obtained from PF simulation is utilized as a boundary condition for calculation. In this study, we focus on the mechanical property, i.e., the stress-strain (S-S) curve of dual-phase steels. Firstly, various morphologies of microstructure observed during spheroidization process from lamella structure are prepared by conventional PF method. Secondary, the S-S curves corresponding to each calculated microstructure are evaluated by the modified secant method [1], where the matrix and inclusion phases are assumed to be ferrite and martensite, respectively. As a consequence, the dataset composed of “microstructure data” and “S-S curve” is generated. From the microstructure data, we extract the following feature amount: volume fraction, interfacial area, genus, connectivity, variance of mean curvature and variance of Gaussian curvature. In order to understand the quantitative relationship between the S-S curves and the microstructure morphologies, the neural network machine learning technique is employed. Input data to the neural network are not only the feature amount above mentioned but also the true strain in the S-S curve, on the other hand, the output data for neural network training is the true stress only. In the current work, 145 pairs of “microstructure data” and “S-S curve” were applied to optimize the neural network system, then the trained neural network which can describe the relation between microstructure and mechanical property was constructed. By using the trained neural network, the sensitivity of each feature amount to S-S curve was estimated, and the following conclusions were obtained: The final stress level of S-S curve is determined mainly by the volume fraction. It is quite interesting that the stress level at the initial rise up stage of S-S curve depends strongly on the connectivity parameter. The connectivity means the spatial continuity of martensite phase. Therefore, the optimization of martensite morphology is a key point for improving the mechanical property of dual-phase steels. Primary Blast Loading Effects on Axonal Deformation

Reuben Kraft*, Harsha Garimella**, Andrzej Przekwas***

*Penn State University, **CFDRC, Inc., ***CFDRC, Inc.

ABSTRACT

Subject-specific computer models (male and female) of the human head were used to investigate the possible axonal deformation resulting from the primary phase blast-induced skull flexures. The corresponding axonal tractography was explicitly incorporated into these finite element models using a recently developed technique based on the embedded finite element method. These models were subjected to extensive verification against experimental studies which examined their pressure and displacement response under a wide range of loading conditions. Once verified, a parametric study was developed to investigate the axonal deformation for a wide range of loading overpressures and directions as well as varying cerebrospinal fluid (CSF) material models. This study focuses on early times during a blast event, just as the shock transverses the skull (< 5 milliseconds). Corresponding boundary conditions were applied to eliminate the rotation effects and the corresponding axonal deformation. A total of 138 simulations were developed - 128 simulations for studying the different loading scenarios and 10 simulations for studying the effects of CSF material model variance - leading to a total of 10,702 simulation core hours. Extreme strains and strain rates along each of the fiber tracts in each of these scenarios were documented and presented here. The results suggest that the blast-induced skull flexures result in strain rates as high as 150-378 s-1. This rapid deformation of the axonal fiber tracts, caused by flexural displacement of the skull, suggests the possibility of rate-dependent micro-structural axonal damage according to the published experimental studies.

Stabilization of Reduced-order Flow Models through Learning-based Closure Modeling

Boris Kramer*, Mouhacine Benosman**, Omer San***, Jeff Borggaard****

*Massachusetts Institute of Technology, **Mitsubishi Electric Research Labs, ***Oklahoma State University, ****Virginia Tech

ABSTRACT

In this talk, we present a learning-based method for stabilization of reduced-order models (ROMs) for thermal fluids, which are challenging multi-physics systems. The stabilization of the reduced-order model is achieved by using Lyapunov robust control theory to design a new closure model. Furthermore, the design parameters in the proposed ROM stabilization method are optimized using a data-driven multi-parametric extremum seeking (MES) algorithm. We show the advantages of the proposed method on numerically challenging test-cases by using the 2D and 3D Boussinesq equations. The results illustrate that closure models can be extended to multi-physics systems, by using multiple design parameters.

Higher Order 2D Virtual Elements for Elastic Materials at Finite Strains

Alex Kraus*, Peter Wriggers**

*Leibniz Universität Hannover, Institute for Continuum Mechanics, **Leibniz Universität Hannover, Institute for Continuum Mechanics

ABSTRACT

The recently developed Virtual Element method shows promise as an alternative to finite element formulations and has gained a lot of attention in the last years due to its flexibility using meshes with convex and non-convex elements. However, for large strain applications this discretization technique has not been established as a standard engineering tool. This is mainly due to the need to stabilize this formulation. Based on the stabilization method proposed by Wriggers et al. 2017, a new method for the evaluation of the stabilizing term for a virtual element formulation was developed in this approach. Furthermore, a higher order formulation for finite deformations was developed.

A 3D Discontinuous Galerkin Cut Cell Immerse Boundary Method: Results and a View on Parallel Efficiency

Dennis Krause*, Florian Kummer**

*TU Darmstadt, **TU Darmstadt

ABSTRACT

In the past, we developed an immersed boundary solver in a cut cell context based on a cut cell (extended, unfitted) Discontinuous Galerkin (DG) discretization. To overcome the difficulty of quadrature on cut cells, we use the hierarchical moment fitting quadrature technique proposed by Müller et al. [1]. For coupled motion we use a simple Lie-Splitting approach for the moving domain. Furthermore, the boundary conditions at the interface are represented by Dirichlet values for velocity in the weak form of the discretization. In first two dimensional calculations we could proof very good agreement with other works in the field of immersed boundary methods for moving body flows. This can be shown for simple static boundary test cases as well as for typical fluid-structure interaction problems like an oscillating cylinder or coupled problems like a disk separating in a vertical channel due to gravity forces. Additionally, the crucial benefit is the save of total degrees of freedom comparing with particulate flow literature. However, also a dependence of the calculated forces on the penalty parameter chosen was discovered. All results mentioned have already been published [2]. For large 3D calculations, it became apparent, that two main topics had to be addressed, in order to reach the aforementioned goal: First, the direct solver MUMPS had been substituted by an iterative solver, i.e. GMRES with a suitable Preconditioning. Second, the total parallel efficiency of the solver had to be increased. Additionally, a dynamic load balancing approach had to be implemented in case of moving boundaries. The presentation will shortly introduce the method. After that, we will focus on suitable preconditioning for the linear equations systems and analyse the bottlenecks of performance arising from large 3D calculations. Acknowledgement: The work of D. Parallel Multigrid Methods for Interface Problems

Rolf Krause*, Patrick Zulian**, Maria Nestola***, Cyrill von Planta****

*Institute of Computational Science, USI, **Institute of Computational Science, USI, ***Institute of Computational Science, USI, ****Institute of Computational Science, USI

ABSTRACT

In this talk, we discuss the design of efficient parallel multigrid methods for contact and interface propblems. Contact and interface problems pose particular challenges for the development of efficient parallel solution methods. On the one hand, the presence of the strongly local non-linearities, which are associated to the interface, requires a global convergence control strategy. On the other hand, in particular for the case of multi-body contact or embedded interfaces, the discretization of the interface itself and of the (non-penetration) constraints at the interface will give rise to additional communication between the different processors. Thus, standard parallelization strategies for standard linear multigrid methods can not be applied directly to contact and interface problems. In this talk, we discuss the difficulties related to global convergence control for the case of parallel multigrid methods. We present different convergence control strategies, which are based on successive energy minimization in parallel and exploit the fact that contact problems can be viewed as constrained minimization problems. Our strategies can be applied in the case of linear as well as non-linear material laws. We furthermore discuss how to build efficiently a parallel and inherently non-linear multilevel method for contact problems. Finally, we explain how to compute in parallel the inter-mesh dependencies at contacting or embedded interfaces. We will treat the case of non-overlapping (contact) as well as of overlapping (embedded interfaces) decompositions. Examples from geo-sciences and from fluid-structure interaction in cardiovascular applications will illustrate our findings.

Generation of Reliable Input Data for a Damage Model Taking Use of a Closed CAE-Chain Containing Material Interfaces

Constantin Krauss*, Siegfrid Galkin**, Luise Kaerger***

*Karlsruhe Institute of Technology (KIT), Institute of Vehicle System Technology (FAST), Part Institute of Lightweight Technology, **Karlsruhe Institute of Technology (KIT), Institute of Vehicle System Technology (FAST), Part Institute of Lightweight Technology, ***Karlsruhe Institute of Technology (KIT), Institute of Vehicle System Technology (FAST), Part Institute of Lightweight Technology

ABSTRACT

Due to their high specific strength and stiffness, continuous fiber-reinforced polymers (CoFRP) are ideal lightweight materials for high performance structural components in the automotive sector. In addition, demands regarding economics, robustness and cycle times of the manufacturing processes are even higher in order to be able to compete with the commonly used metallic materials in large batch production. Such processes, for instance the Resin Transfer Molding, are further divided into a sequence of several sub processes containing draping, infiltration and curing steps. Developing and extending simulation models for these processes has been topic of numerous investigations in the past and present time and are quite well understood. Since in the field of composites, both the material and the actual part are results of the manufacturing, the material's history is crucial for the final structural performance. Occurring changes in fiber orientation, fiber volume content and additional effects such as fiber undulation or wrinkle formation and also remaining residual stresses need to be taken into account to avoid oversized or defective structures. Since material constitutive behavior, physics or reasonable mesh topology and size typically vary, different specialized software for each of the process steps is usually used. Therefore, the virtual interfaces between the individual simulation steps are going to play a key role in the future. Within these interfaces the exchange and transfer of relevant geometric and material data is managed. In the present moment, significant effort is required to develop and implement such interfaces, which are usually tailor-made for the current problem and not applicable to new cases. Within the EU research project ITEA-VMAP this issue is addressed by creating a new interface standard for virtual material modelling. The aim of this concept is to ease and accelerate the building of virtual process chains and thus of reducing the product's TTM. In this work, the virtual manufacturing route of an exemplary composite structure based of unidirectional non-crimp fabric reinforcement is presented. Hereby, the main focus is on the interface formulation and realization. It is demonstrated how the information flow within the CAE-chain is accomplished and how draping effects affect e.g. permeability, thermal expansion and strength. Eventually, a newly developed damage model is fed with the provided parameters resulting from the previous simulation steps. The main goal is to assess the impact on the load bearing capacity compared to computations neglecting the material's prehistory.

ABSTRACT

We present efficient way of solving incompressible Navier-Stokes Equations (NSE) for industrial applications involving turbulence modelling[1]. We named our methodology as Direct FEM Simulation (DFS)[2] which is based on the General Galerkin (G2); and it is defined by finite element method (FEM) with piecewise linear approximation in space and time, and with numerical stabilization in the form of a weighted least squares method based on the residual. The incompressible Navier-Stokes Equations (NSE) are discretized directly, without applying any filter. Thus, the method does not result in Large Eddy Simulation (LES) filtered solutions, but is instead an approximation of a weak solution satisfying the weak form of the NSE. This means no explicit turbulence model is used, and the effect of unresolved turbulent boundary layers is modeled by a simple parametrization of the wall shear stress in terms of a skin friction. Which leads to getting small skin friction on the boundary for the higher Reynolds number (in particular turbulence modelling) thus favors the slip boundary condition, and it requires not having solved costly (computationally expensive) boundary layer resolution. And another main advantage with our methodology is that adaptivity, which is achieved by doing posteriori error estimation using adjoint techniques[2], and it is defined as a goal functions, for example, lift and drag. This minimizes effort of computational domain manual mesh refinement. Our approach and methodology has been well tested against typical scientific and industrial benchmark models[2,3,4], in particular we have previously participated in HiLiftPW-2, HiLiftPW-3 and HiOCFD5 (tandem sphere test case). For example, even how one can get benefit (computational cost) using our methodology over higher order methods. And also we present parallel post processing based on the task parallelization using the VisIt[5] visualization tool. [1] FEniCS (2003), ‘Fenics project’, http://www.fenicsproject.org. Modeling of Damage and Crack Growth in Semi-Crystalline Polymers

Martin Kroon*, Eskil Andreasson**

*Linnaeus University, **Blekinge Technical University

ABSTRACT

Crack growth in semi-crystalline polymers, represented by polyethylene, is considered. The material considered comes in plates that had been created through an injection-molding process. Hence, the material was taken to be orthotropic. Material directions were identified as MD: molding direction, CD: transverse direction, TD: thickness direction. Uniaxial tensile testing was performed in order to establish the direction-specific elastic-plastic behaviour of the polymer. In addition, the fracture mechanics properties of the material was determined by performing fracture mechanics testing on plates with side cracks of different lengths. The fracture mechanics tests were filmed using a video camera. Based on this information, the force vs. load-line displacement could be established for the fracture mechanics tests, in which also the current length of the crack was indicated, since crack growth took place. The crack growth experiments were then simulated using Abaqus, where crack growth was enabled by use of a cohesive zone. The force-displacement-crack length data from the experiments could be well reproduced in the simulations, where different model parameters for the cohesive zone were explored. Furthermore, the direction-specific work of fracture had been established from the experiments and these energies could be compared to the values of the J-integral from the simulations for the different crack lengths.

Mesh Generation Techniques for Converting Triangular Meshes to Quadrilateral and Mixed-element Meshes with Applications to Shallow Water Flow

Ethan Kubatko*, Dominik Mattioli**, Dylan Wood***

*The Ohio State University, **The University of Iowa, ***The Ohio State University

ABSTRACT

In this talk, we discuss the development and implementation of a new, simple indirect methodology for producing high-quality quadrilateral (quad) and quad-dominant meshes from any pre-existing, unstructured triangular mesh. One of the primary motivations for this work is to provide a tool for generating meshes that can be used within a discontinuous Galerkin (DG) finite element framework for modeling shallow water flow — a setting where meshes of mixed-element composition can be easily accommodated and where the computational advantages of using quad elements have been demonstrated [1]. Employed techniques include: A strategic merging sequence of neighboring triangular element pairs to form quads, several topological operators designed to improve the quality of the resulting quad elements and a direct (i.e., non-iterative) smoothing method to improve overall mesh quality. When paired with an existing triangular-element mesh generator, ADMESH+ [2], this new methodology results in a mesh generation tool capable of automatically producing high-quality triangular, quad and mixed-element meshes within one framework. Several example quad and quad-dominant meshes produced from the mesh generation tool will be presented, and numerical results of shallow water simulations obtained from the quad and quad-dominant meshes will be compared to the results obtained from their parent triangular meshes in terms of overall accuracy and efficiency. Meshless Remap for Earth System Models

Paul Kuberry*, Pavel Bochev**, Kara Peterson***

*Sandia National Laboratories, **Sandia National Laboratories, ***Sandia National Laboratories

ABSTRACT

Global Earth System Models comprise multiple components, representing a diverse set of physical phenomena and employing different types of discretizations adapted to the particular scales and features of the underlying physical phenomena. As a result, the coupling of these components requires information exchanges (remap) between codes, which involve fields defined on different types of meshes and possibly having different representations, e.g., finite element vs. finite volume, or node-centered vs. cell-centered. Typically, the coupling takes place over a shared subdomain boundary, resulting in interface discretizations that are generally mismatched. For such couplings, a mesh-free approach to data transfer offers an attractive alternative to traditional, mesh-based remap. In this talk we present a flexible data transfer tool, employing Generalized moving least squares (GMLS), and which can handle a wide range of ``native'' field representations. GMLS is a meshless reconstruction technique for approximating a target functional from nearby neighbor information, which makes it particularly well-suited for our purposes. The GMLS data transfer tool is based on the recently developed Compadre meshless toolkit, which provides a wide range of utilities for mesh-free discretizations of PDEs. Compadre utilizes the Trilinos software stack to balance workloads over processors, execute k-d tree searches, reconstruct functionals using GMLS, and to provide many additional capabilities for meshfree PDE discretizations. The talk will highlight the ability of the toolkit to also support coupling codes such as components of Earth system models, by allowing for processor assignment of coordinates or sites where information is needed from the peer program. This information is constructed using neighbor information in the peer program and then transferred back. Transfer in this way allows for completely independent distributions of field data in each code being coupled. Numerical results will be presented demonstrating exact transfer of specific orders of polynomial solutions on the sphere, as well as the approximation error introduced when the solution being transferred is not within the span of the basis for the reconstruction.

301 28 Czech Republic

Key words: Blade Tip-Timing, Sensors, Calibration, Steam turbine, Vibration limits

Abstract. Blade Tip-Timing measurement becomes more and more valuable because power generation market is changing to the peak-load market. Today steam turbines have to full-fill high efficiency and reliability demand as well as increasing of number of cycles or operating under wide operational range which include windage or low load operation. The higher level of blade vibration is more common for windage and other non-nominal regimes. Blade Tip-Timing measurement offer solution for long term monitoring and safety operation.
The new last stage steam turbine blades have been developed with state of the art design features. The last stage moving blades are designed with integral shroud, mid-span tie-boss connection, and fir-tree dovetail. The blades are continuously coupled by blade untwist due to centrifugal force, and thus decreased vibrations and increased structural damping are provided. Unfortunately measurement of shrouded blades is much more complicated and the sensor to blade calibration has to be performed.
The Blade Tip-Timing measurement and sensor calibration is described in the paper. The calibration of magnetoresistive, optical sensors and eddy-current sensors was performed. The induction and optical reflection phenomena is described with their impact to shroud edge detection. The detection of shroud edges and its angle seems to be important in terms of calibration between tip deflections to high air foil stress identification. The comparison between the individual types of sensors is presented as well as the real results from 270MW steam turbine operation in wide operational range. The motivation to use multiple sensors and provide their calibration is reduced uncertainty of Blade Tip-Timing which is presented in many publications.

1 INTRODUCTION

In 2009, a new 48“ steam turbine last stage blade (LSB) was developed by Doosan Skoda Power and in 2013 a new 42” LSB for 3000 RPM and high backpressure was developed with the application of new design features. Using modern computational instruments, airfoils with high flow efficiency were designed. Successful detuning of natural frequencies with respect to harmonics of rotational frequency has been achieved for both blades by using interconnecting elements near the mid-span and at the tip of the blades. Friction forces among the contact elements result from the constraint of blade untwist induced by centrifugal force. The mechanical properties of LSB were measured under rotation in a Campbell testing rig (vacuum chamber with rotating bladed disk and some source of blade excitation). Measurement proved that blades are out of synchronous resonances up to 7th harmonic frequency.

Synchronous excitation is the most common excitation in terms of the steam turbine blades. This excitation is closely related with circumferential asymmetry, blade passing and unbalance. On the other hand, resonances with non-synchronous excitation can occur as a result of aerodynamic excitation. Avoiding that is quite demanding task, because even very small aerodynamic excitation forces with wide frequency range can excite blades if the damping is insufficient. A big amplitudes of vibration during ventilation conditions was present several times as well as unstalled flutter observation during power output increase [5]. 3D unsteady CFD methodology under ventilation conditions was published by Megerle in 2012 [1]. Rotating aerodynamic excitation was measured and confirmed by CFD simulation, unfortunately there are still some unpredictable cell patterns. Previous study made by Shnee in 1974 [6] shows that there is a dynamic stress 2-3 times higher than the dynamic stresses at rated conditions in the range of 30 – 60 % of the nominal volume flow due to aerodynamic induced vibrations during ventilation.

From time to time customers want to operate the turbine in extraordinary conditions which can cause unpredictable blade excitations. These excitations have impact on dynamic stress of blades and reduced blade lifetime. Based on this, it was decided to measure blade vibration in a wide range of operation conditions in the power station and reduces mechanical stress of rotating blades thereby increasing their service life.

Damage of the blades causes changes in their frequency characteristics, which are measured using a contact or contactless method. The contact measurement by strain gauges provides direct information about the blade stresses during operation. However, this method is not suitable for long-term measurements, because the sensors service life is short in a corrosive environment. Furthermore, it is very difficult and expensive to monitor all blades of the bladed disc.

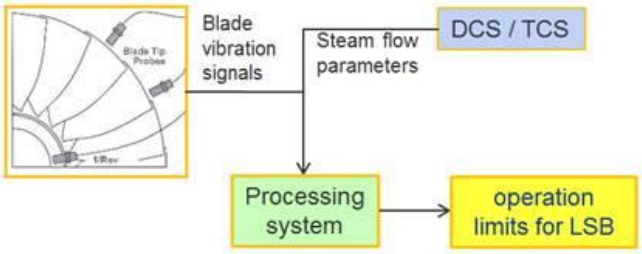

Figure 1 - Blade vibration monitoring system components

Noncontact measurement methods based on analysis of blade tip passing times are used for blade vibration measurement - blade tip-timing (BTT). The schematic description of BTT is shown on Figure 1. This method was used in 1970's for the first time. The manufacturers use abbreviations NSMS (Non- Intrusive Stress Measurement System), BSSM (Berührungslose Schaufelschwingungsmessung) or usually Blade Tip Timing. BTT method is a cheaper alternative with a long-term instrumentation in comparison with strain gauges which offer a direct measurement of the blade stress but with a very short instrumentation lifetime. The BTT approach is based on sensors which are located circumferentially around bladed disk, radially mounted in the stator, watching tip of trailing edge [3, 4, 5]. This arrangement enables the measurement of blade tip passes. The system measures and analyses time differences of blades passing along the sensor position. The sensor itself is placed very close to the blade (order of ones-tens of millimetres depending on technology of the sensor), in order to guarantee fast response time and high sensitivity. The passing blade generates a trigger pulse which is captured by a high resolution time counter. All the data or timestamps are analysed and at the output of the system information on the blade vibration is provided.

It is important to monitor the blades frequency characteristics during turbine run-up, run-down and power changes. The measurement of vibrations provides information about blade deflection and blade residual lifetime. The long-term measurement of blade deflections is important for planning shutdowns and optimization of the maintenance cost and operation of the turbine.

Blade deflections are determined by differences between the real and expected passage times of the blades under the sensors. The deflection of the specific blade is sampled once per revolution. An antialiasing filter cannot be used in the measurement chain because the turbine rotation frequency is in fact the sampling frequency of the blade rotation movement and furthermore, the rotation speed changes. For these reasons, the vibrations of the specific blade are measured in a limited frequency range with lots of data mirrors at higher frequency and lower frequency resolution. Increasing the number of sensors does not often bring results adequate to expended resources.

Instead of single blade behaviour analysis, behaviour of the whole bladed disc could be analysed. The deflections are sampled by the passages of all blades. Then, the width of the frequency band is sufficient and aliasing doesn’t manifest itself so much. The all-blade spec-

trum, which is the spectrum involving all blades of one disc, is calculated for each sensor from deflections measured for all blades passed under the sensor using short-time Fourier transform. Consequently, cross spectra are calculated from couples of the all-blade spectra from different sensors.

To obtain correct information about vibrations of shrouded blades, it was necessary to develop reliable measuring equipment for the shrouded blades. The key factor is to use adequate sensors [13, 14].

2 REQUIREMENTS FOR NON-CONTACT VIBRATION MEASUREMENTS ON SHROUDED BLADES

Observing the motion of rotating and vibrating blades in turbomachinery is a relatively demanding task. The sensors have to operate properly and precisely in a harsh environment characterized by temperatures up to 250°C and relative humidity of 100% (LP part of steam turbine). Concurrently, long-term stability, high accuracy and sensitivity of the sensors are required. Most present systems are therefore focused on the application of non-contact methods which can operate on a variety of principles. The limiting factor for non-contact measurement of blades vibration is the sampling frequency fs. The sampling level has in BTT a significant influence on determining the vibration amplitude of the blades. Maximum resolution of the blade deflection is described by the following relation:

$$\Delta_a = \frac{2\pi \cdot r_{senz} \cdot f_{rot}}{f_s}, \tag{1}$$

where r_{senz} is the radius (measured from the center of the rotor) on which the sensor is placed. f_{rot} is the maximum rotational speed of the bladed disk in the measurements (typically 50 Hz). To illustrate the dependence between sampling rate and blade deflection amplitude resolution, the above relationship was used to provide the following table computed for rotation frequency of 50 Hz:

Table 1 - Resolution base on sampling frequency

f_s	blade 1220mm + 900mm rotor radius = 2120mm
100kHz (standard acquisition systems)	6660.2 μm
1MHz	666.0 μm
8MHz (oscilloscope standard)	83.2 μm
100MHz	6.6 μm
500MHz	1.3 μm

Table 1 shows the blade vibration resolution. It is clear that, for example, system resolution approaching units of microns should work with sampling frequencies of 500 MHz and

higher. Demand for a maximum resolution sensor should always be related to the largest bladed disk of the machine. For smaller diameters better resolution of measured deflection is always guaranteed, sampling frequency maintains.

The table above also shows that standard acquisition systems are not appropriate for BTT measurements (usually sampling frequency up to 100 kHz - 200 kHz). The biggest resolution of the measurement in such a case is in the order of millimetres, which is beyond the expected oscillatory behaviour of shrouded blades. For general diagnostic systems, which are able to monitor blades and evaluate their level of stress, it is necessary to use special hardware that allows the required sampling rate - hundreds of MHz For the measurement of LSB, which is presented in this paper, the 200MHz system was used in combination with several types of sensors. This system seems to be sufficient to monitor LSB shrouded blades with vibration amplitudes 10 times under fatigue strength.

3 EDDY-CURRENT SENSOR CALIBRATION

The eddy-current sensors are most valuable in terms of robustness and cost. The principle is very simple see [13, 14]. There are magnet and coil in the sensor case. When the blade passes the sensor the eddy-current in the blade create magnetic field which induced the voltage in the sensor itself. The following equation describes the induced voltage in the sensor.

$$\mathrm{V} = \frac{\mathrm{k}\times\mathrm{RPM}\times\mathrm{B(T)}\times\mathrm{f}\left(\mathrm{RPM},\mathrm{d}_{\mathrm{sensor}}\sqrt{\lceil\mu\delta\rceil_{\mathrm{sensor}}\,(\mathrm{T})}\right)\times\mathrm{d}_{\mathrm{BLADE}}\sqrt{\lceil\mu\delta\rceil_{\mathrm{BLADE}}\,(\mathrm{T})}\times\mathrm{T}_{\mathrm{sensor}}}{(\mathrm{gap}+\mathrm{r})^{6}}, \qquad (2)$$

where V is the blade pulse voltage, RPM is the rotor shaft speed, k is the calibration factor, B(T) is the permanent magnetic field, which varies with temperature. The term f (.) describes the lowpass effect of the sensor signal due to eddy currents in the sensor itself, resisting the change in magnetic field. The frequency of the low pass effect is determined by the μσ product of the material in the sensor, which varies with temperature. The term $\mathrm{d}_{\mathrm{BLADE}}\sqrt{\lceil\mu\delta\rceil_{\mathrm{BLADE}}\,(\mathrm{T})}$ describes how the pulse amplitude increases with the μσ product and the thickness of the blade. The $(\mathrm{gap}+\mathrm{r})^{6}$ term relates how the pulse amplitude changes with changing gap. For the practical usage the equation 2 can be simplified as equation 3.

$$gap = K\left(\frac{RPM}{V-V_{start}}\right)^{1/6} - r, \qquad (3)$$

To validate blade sensor model the computational model was created in ANSYS Maxwell – electromechanical FEM based simulation software. This model contained three blades (with cyclic symmetric condition), sensor and stator ring. The magnetic field around of the sensor is excited by a permanent magnet which is the part of the sensor. Magnetic flux lines are closing across the stator ring and blade shrouds. Changes in magnetic flux, caused by the shrouds rotation, are detected by the sensor coil.

By this model it was tried to cover the real conditions in a steam turbine. The blades rotate 50Hz that implies the tip speed 640m/s. This speed requires the simulation time and the simulation time step which had to be quite small.

For final evaluation the triggering algorithm was used. It was the same triggering algorithm which had been used for real BTT data. It is a very robust algorithm which contains high pass and low pass filtering, arm level which activates a trigger and finally the trigger which waits for a falling or rising edge going across the 0 level. (The algorithm was taken from HoodTech BTT acquire SW, because the authors have very good experience with it on-site).

This algorithm finally provides a time of arrival of individual blades which correspond to actual blade position. In next figure (Fig. 2) there are the times of arrival shown by cross markers (one cross for one axial position). It can be seen that these crosses correspond to outgoing edge of the shroud bellow the sensor coil.

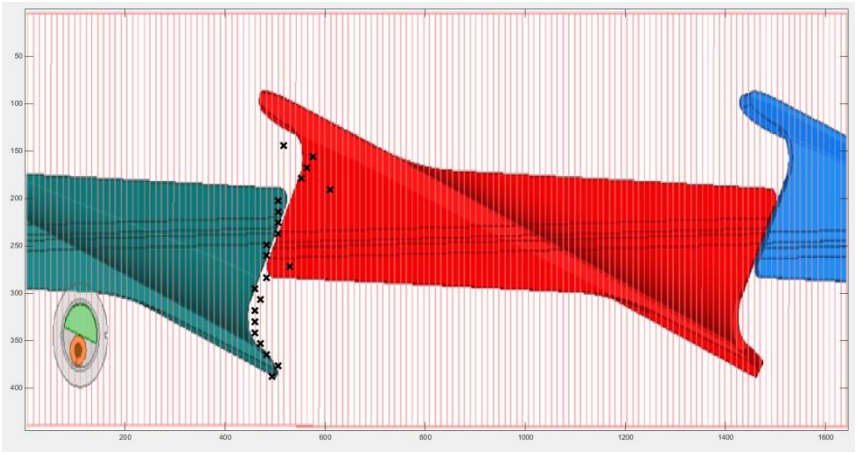

Figure 2 – Detection of the blade based on calculated signals and triggering algorithm

3.1 Experimental validation

The numerical calculation of the eddy-current sensor provides suitable solution. The next step was to verify the calculation by the measurement. The bladed disk was installed in to the Campbell machine. The Campbell machine is the vacuum chamber with rotor and one stage blade. The blades rotate in the vacuum with nominal speed and the vibration are excited by the electromagnets or oil jets.

The eddy-current sensors were installed into the vacuum chamber and used for measurement of time of arrival. The raw signals (before triggering algorithm usage) were recorded and then compared with calculation signals. The following figure 3 shows the comparison.

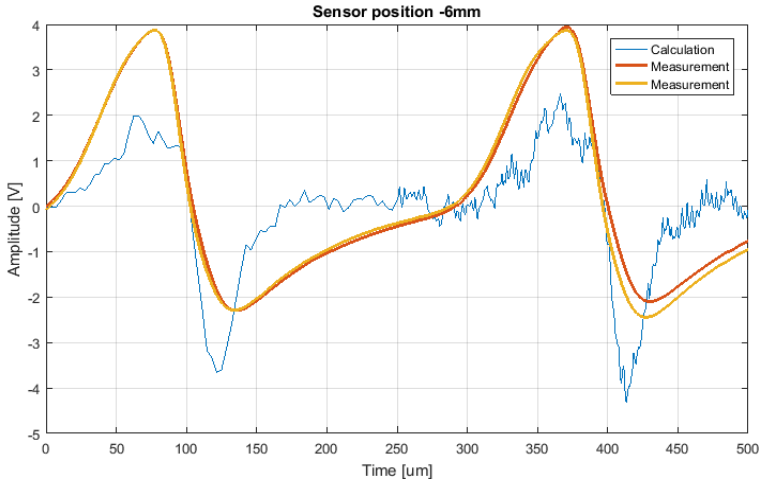

Figure 3 – Comparison of calculated signal (blue) and the measured signal from eddy-current sensor (red and yellow curves)

It is easy to see that calculated and real signals have same trends. The measured signals have lower noise than calculated one. The authors assume that the noise in the calculation is there because the 2 different meshes were used for the calculation – one for blades and second for electromagnetic surroundings. On the other hand the measured curve looks very smooth, it is happen because whole sensor system is behave like low pass filter.

4 MEASUREMENT IN POWER STATION UNDER REAL AND SPECIAL OPERATIONAL CONDITIONS

The crucial task for blade monitoring is to determine blade vibration limits (BVL) which are basically dependent on blade mode shapes. In case of integrally coupled blading the nodal diameter also affects vibration limits.

BVL are evaluated base on blade material fatigue limit (Goodman diagram) and safety factors. When the safety factors are applied then two critical blade locations are distinguish: airfoil and dovetail.

Maximal allowable cyclic stress is defined as

Airfoil $$\sigma_{max} = \frac{\sigma_F}{S_b S_e}, \quad (4)$$

Dovetail $$\sigma_{max} = \frac{\sigma_F}{S_b S_e S_f} \quad (5)$$

Where:

σ_F Fatigue strength reflecting mean stress preload (Goodman diagram)

S_b Basic safety factor

S_e Safety factor for environment

S_f Safety factor for fretting

Based on the FEM modal analysis the ratio R between dynamic cyclic stress at critical location and vibration amplitude of monitored tip location is determined for each mode shape and nodal diameter.

Maximal allowable vibration amplitude of the blade tip is determined as:

$$U_{max} = \frac{\sigma_{max}}{R}, \tag{6}$$

The BTT sensors monitor vibration only in circumferential direction therefore U_{max} has to be recalculated into proper direction in order to be used as BTT vibrational limits.

Figures 4 and 5 present typical Umax limits and BTT limits YC for the long LSB. Fatigue strength σ_F was determined based on the measured Wohler curve and Goodman diagram.

Figures 4 and 5 show that the most critical location from fatigue view is blade dovetail (root neck). This conclusion is also supported by the fact that the most cracks occur at the blade dovetails.

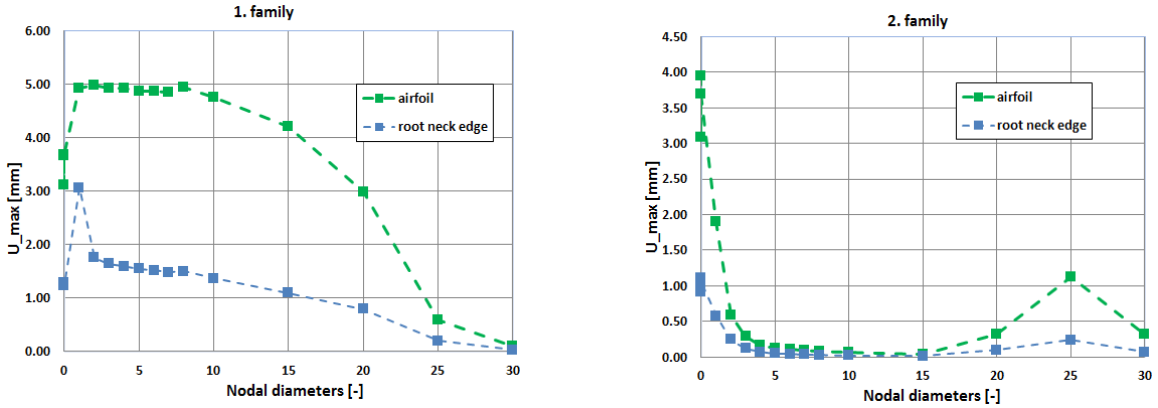

Figure 4 – Maximal alloable vibration amplitude at the blde tip for the first and second mode shape. Two critical location are depicted

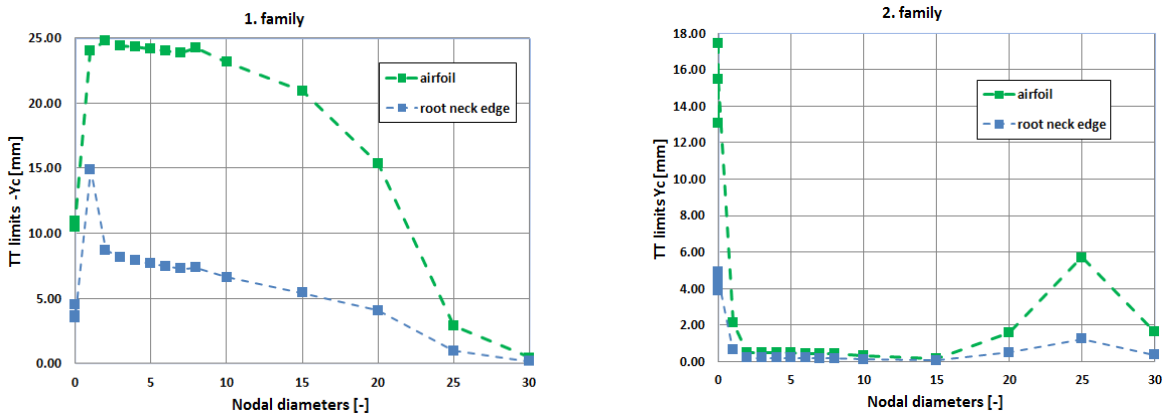

Figure 5 – BTT limits amplitude at leading edge for the first and socend mode shape. Two critical location are depicted

4.1 Field vibration monitoring setup

In early 2013 biaxial magnetoresistive, standard eddy-current and green laser optical sensors were installed into the 270 MW steam turbine. The sensors were located in LP part and watched LSB tip trailing edge. Totally 18 sensors were installed non-uniformly around the half of bladed disk. There were 5 eddy-current sensors, 7 biaxial magneto-resistive sensors (2 pairs of 3 involved sensors and individual dual sensor) and 6 optical sensors. Blade tip timing system from Hoodtech was used with 200MHz sampling frequency and it was able to measure up to 32 channels. The system allows setting up a different trigger for each sensor which was necessary because the physical principle of the sensors were different. The differences between signals from optical and electrical based sensors are shown in Figure 6.

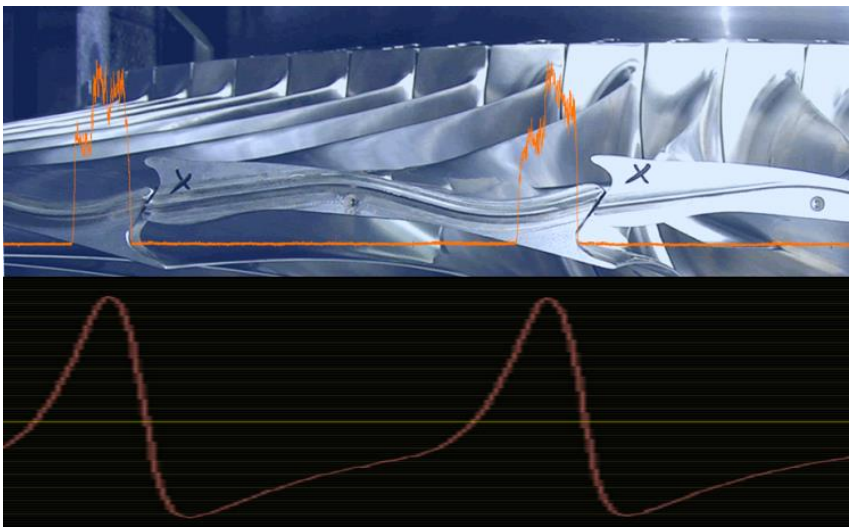

Figure 6 - different signal for triggering – upper picture represents optical signals and bottom picture is signal from eddy-current sensor

In 2016 on field blade monitoring was carried out at 135 MW steam turbine power plant. Seven different measuring runs were undertaken, see table 2. During the each run the back-pressure in condenser was gradually increasing from 10kPa to 42kPa. Both vacuum pumps were switched off one by one as required therefore vacuum drop control was limited however vacuum decay tendency (up to 2kPa/min) was still acceptable.

Table 2 - Measurement runs

1	1800rpm	Pre-heating of the turbine
2	3000rpm, 0MW	Large portion of steam was bypassed
3	20MW	Power control, certain portion of steam was bypassed
4	40MW	Power control, certain portion of steam was bypassed, LP regeneration switch on
5	65MW	Power control, LP regeneration switch on
6	90MW	Pressure control, not enough steam to maintain constant power
7	135MW	Pressure control, not enough steam to maintain constant power

Totally seven tests were done. Turbine reached seven different power outputs and then the back pressure was gradually changed (vacuum in condenser decrease from 0.05 up to 0.5 bar).

All measured data were evaluated by in-house code that was created for this purpose in MATLAB. It was found out that the blades vibrated under all operating regimes that were monitored:

- dominant vibration : 1st mode family, nodal diameters from 4 to 7 , ND5 – the most excited
- 2nd mode family was not observed

BTT vibration amplitudes were plotted in graphs with respect to nodal diameters see figures 7 to 8. Figures 9 show maximal BTT vibration amplitudes respectively.

Maximal vibrations in figure 9 are likely the most relevant amplitudes that should be focused on since they represent sum of all amplitudes but mostly those dominant related to ND4 to ND7. Even if the maximal vibration amplitudes are not presented continuously but only about 30% the total time a number of cycles related to these amplitudes are still sufficiently high in terms of high cycle fatigue (HCF).

The major output from the field monitoring of LSB is presented in the figures 7 to 9. It shows BTT amplitudes versus backpressure and volumetric flow. Red and black lines depict alarm and trip limits respectively. The colormap area in the above mentioned figures is limited by boiler capacity (mass flow) in other words the higher volumetric flow regimes for high backpressure than 42kPa are not reachable at this power plant.

After the evaluation of all data it became clear which type of sensor is the best. For operation with high steam parameters the laser sensor provides very accuracy signals without any electrical noise. On the other hand when the steam was wet and there were small water drops the signal was insufficient and it was not possible to measure blade vibration. Standard eddy-current sensors and newly developed magnetoresistive sensors [11] provided signals all the time. The differences between them could be shown only in all blade spectrums. The spectrum from biaxial magnetoresistive sensor is better in terms of signal to noise ratio. The 50 Hz and multiples of 50 Hz are very poor in spectrum of magnetoresistive sensor.

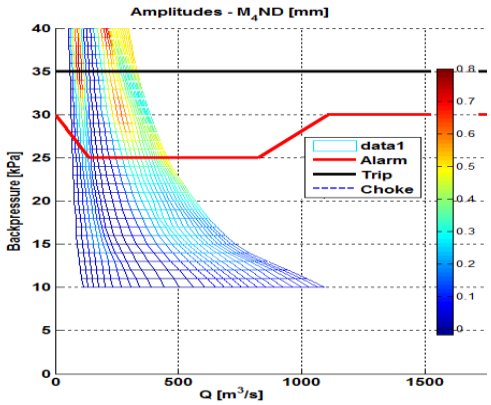

Figure 7 - TT vibration amplitudes (0-peak) for ND4

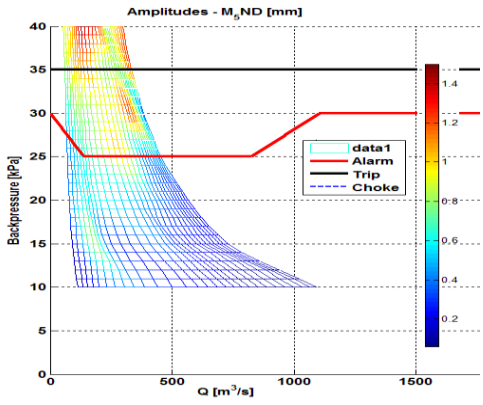

Figure 8 - TT vibration amplitudes (0-peak) for ND5

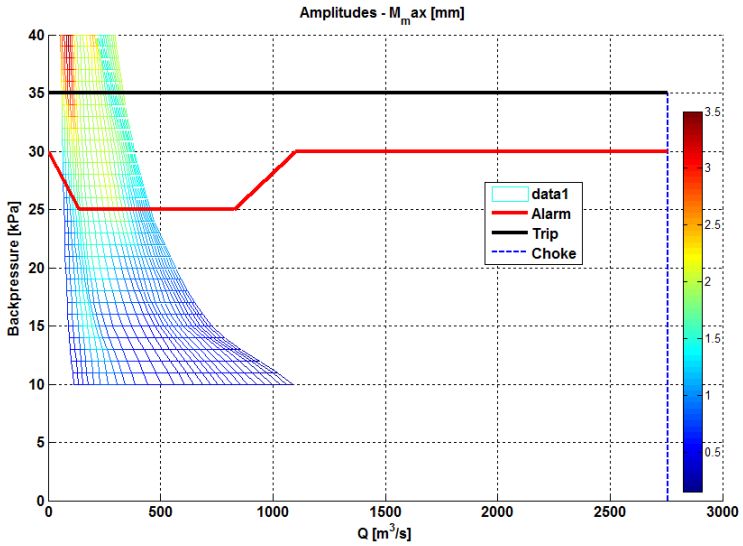

Figure 9 - BTT vibration amplitude - maximal from signal envelope (0-pk) versus backpressure and volumetric flow

5 CONCLUSION

The biaxial magnetoelectric and optical sensors have proven successful in all installations. The sensors are designed for operation under a long-term temperature of 200°C and a short-term temperature of 250°C. Using permanent magnets in MR sensors as the source of the magnetic field simplified the sensor construction and increased its reliability. The most favourable properties of the group of magnetoelectric sensors emphasized advantages of magnetoresistive sensors, which are characterized by high accuracy and sensitivity to displacement, wide frequency bandwidth (0 to 300 kHz) and a very important feature, which is the independence of the sensor output voltage magnitude on the speed of a blade passage. The advantage of this feature is that the sensors can be calibrated statically, for example using a positioning facility. The optical sensors with green laser source have been used in steam turbine with pretty good success. There are still some operational conditions in wet steam environment when the signal noise ratio is not good enough. Eddy-current sensors provide high quality signal as well and it was proven that it can be used for shrouded blades.

Several types of LSBs were measured under real and under special operational conditions. It was found out that the blades vibrated under all operating regimes that were monitored and the installed sensors were capable to identify the tip blade vibration.

It was proved that the blades can be operated in a wide range of operational conditions and they are resistant against high vibration.

The figures 7 - 9 proved Shnee hypothesis [7] that vibration in ventilation is 2-3 times higher. The windage condition are worst in terms of vibration which are 3 times higher than vibration at 100% volume even more the temperature increase dramatically.

Key words: Plain-woven composite, Nesting, basic cell, Homogenization, Viscoplasticity.

Abstract.A basic cell modeling method is newly developed for the homogenization analysis of plain-woven composites with nesting. For this, based on the periodicity and point-symmetry of internal structures of plain-woven composites with nesting, a hexagonal prism-shaped basic cell and its boundary conditions are proposed. The basic cell and boundary conditions are then introduced into the homogenization theory for nonlinear time-dependent composites developed by the authors. Using the present method, elastic-viscoplastic behavior of a plain-woven glass fiber-reinforced plastic (GFRP) composite with nesting subjected to on- and off-axis loading is analyzed.In the analysis, the present method is successful in significantly reducing the analysis domain, and in achieving the modeling of a high volume fraction of fiber bundles caused by nesting. This cannot be attained if conventional cuboid cells are employed as analysis domains. Moreover, it is shown from the analysis results that the present method accurately predicts experimentally observed macroscopic elastic-viscoplastic behavior of the plain-woven GFRP composite with nesting.

1 INTRODUCTION

Plain-woven composites have many positive features, for example, high specific strength, high specific stiffness and good formability. Therefore, they have been used as primary structural members in many industrial fields such as the aerospace, auto and energy-related industries. Plain-woven composites are generally produced by stacking plain fabrics and impregnating them with polymer materials (Fig. 1). During this forming process, fabric layers are not necessarily

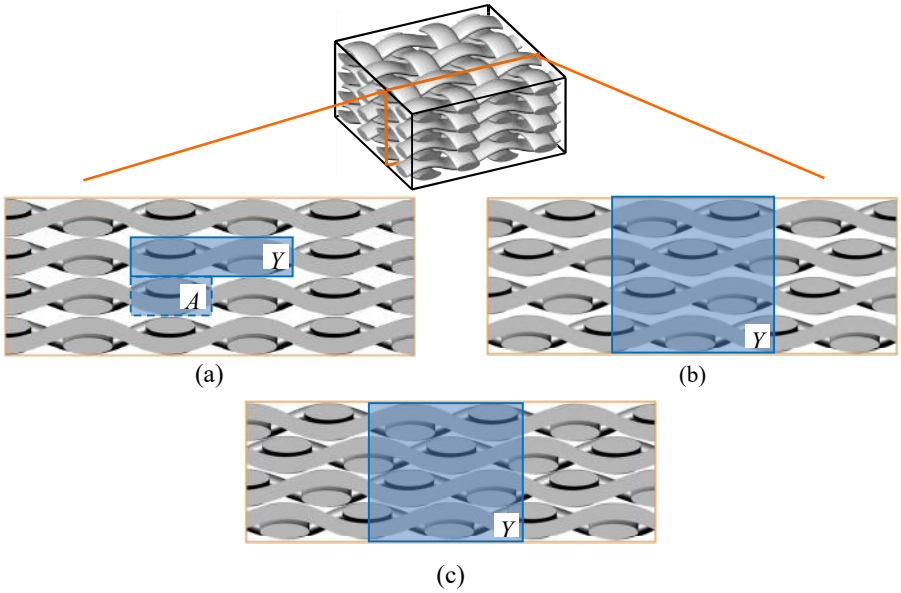

Fig. 1. Microstructures and unit cells of plain-woven laminates; (a) without misalignment, (b) with misalignment of 1/4 unit cell length, (c) with nesting.

aligned (Fig. 1(a)), but can be shifted in the in-plane directions (Fig. 1(b)), which will be referred to as "laminate misalignment". Moreover, compression in the forming process causes the fabric layers to press into each other in the stacking direction. Consequently, complicated internal structures as illustrated in Fig. 1(c), which are generally called "nesting", can occur in plain-woven composites [1-5]. It is known that the nesting can affect the mechanical properties of plain-woven composites, which is not limited to elastic properties such as initial stiffness [5-8], but extends to inelastic properties such as damage behavior and strength [9]. Therefore, we should consider the effects of nesting when analyzing the mechanical properties of plain-woven composites.

For such mechanical analysis of plain-woven composites with nesting, numerical unit cell analysis based on the finite element method (FEM) or homogenization theory [10] is considered as one of the most promising methods. This is because it can explicitly take into account the nesting structures in plain-woven composites. Such analysis, however, encounters two main difficulties. One is how we can easily generate unit cell geometries and FE meshes for unit cells of plain-woven composites with nesting. In general, the aforementioned complicated internal structures of plain-woven composites with nesting make it difficult and cumbersome to generate their unit cells and FE meshes. The second difficulty is that enormous computational costs are required for the analysis because unit cells with nesting basically become much larger than that without nesting due to the restriction of the periodic boundary condition (see the unit cells *Y* in Fig. 1). This can be a critical issue, especially for nonlinear analysis accompanied by incremental computation. For these reasons, the nesting has been ignored in many unit cell analyses [11-13] including our previous studies [14-16].

To overcome the above-mentioned difficulties, some researchers developed the methods to generate geometries and FE meshes of unit cells of woven composites with nesting using micro-computed tomography(CT) or scanning electron microscope (SEM) digital images [17-20]. These methods provided easier generation of realistic geometries for unit cells, e.g. shapes of

fiber bundles and degree of nesting. However, the number of elements in the unit cells became considerably large to obtain appropriate solutions, resulting in application of the methods only to two-dimensional or elastic analyses. In addition, it is difficult for the image-based modeling methods to guarantee the periodic connectivity of unit cells.

In this study, a basic cell modeling method is newly developed for the homogenization analysis of plain-woven composites with nesting, and is applied to an elastic-viscoplastic analysis of plain-woven glass fiber-reinforced plastic (GFRP) composites with nesting. For this, focusing on the periodicity and symmetry of internal structures of plain-woven composites with nesting, a novel basic cell and its boundary conditions are proposed. The basic cell and boundary conditions are introduced into the homogenization theory for nonlinear time-dependent composites developed by the authors [21-23]. The proposed method is then applied to an elastic-viscoplastic analysis of plain-woven GFRP composites with nesting subjected to on- and off-axis loading. Comparing the analysis results with experimental data, we validate the present method.

2 BASIC CELL FOR PLAIN-WOVEN COMPOSITES WITH NESTING AND HOMOGENIZATION THEORY

2.1 Introduction of the basic cell and properties of internal distributions

We consider a plain-woven composite with nesting on the Cartesian coordinates y_i ($i=1,2,3$) as illustrated in Fig. 2, in which each plain fabric is assumed to possess the same degree of nesting in the y_3 - y_1 plane. The composite is assumed to be subjected to a macroscopically uniform load, and to deform infinitesimally. Then, not a conventional cuboid cell [10-16] but a hexagonal prism cell shown in Fig. 2, which will hereafter be called "basic cell A", is defined as an analysis domain. The boundary of A, Γ, is divided into Γ_α ($\alpha=1, 2, \ldots, 8$) as depicted in Fig. 3,where Γ_1 - Γ_4 are sequentially numbered in the counterclockwise direction from the upper right to the front boundary facetsas indicated in Fig. 3(a), and Γ_5 - Γ_8 are also sequentially numbered in the counterclockwise direction from the lower left to the rear boundary facets as indicated in Fig. 3(b). It should be noted that A is much smaller than the unit cell Y [11, 13, 15] generally employed in the homogenization analysis on the basis of the so-called Y-periodic boundary condition.

Now, the microscopic velocity field $\dot{u}_i(\boldsymbol{y},t)$ in A is expressed as [10]

$$\dot{u}_i(\boldsymbol{y},t)=\dot{F}_{ij}(t)y_j+\dot{u}_i^{\#}(\boldsymbol{y},t), \tag{1}$$

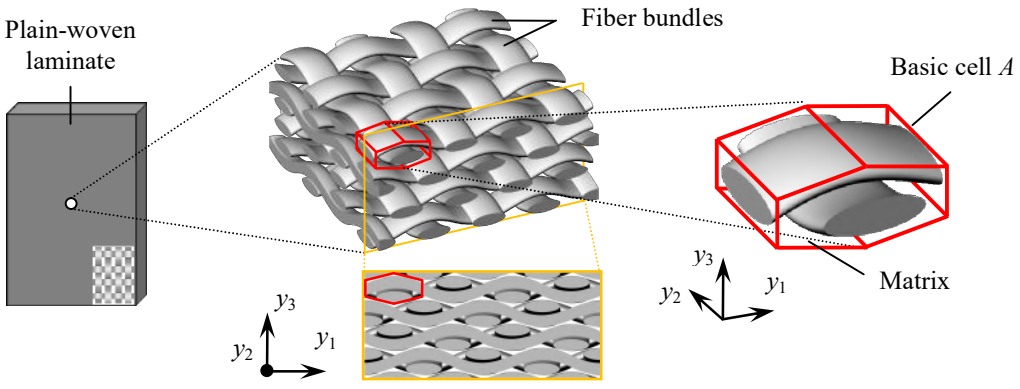

Fig. 2. Plain-wovencomposite with nesting in the y_3 - y_1 plane and basic cell A.

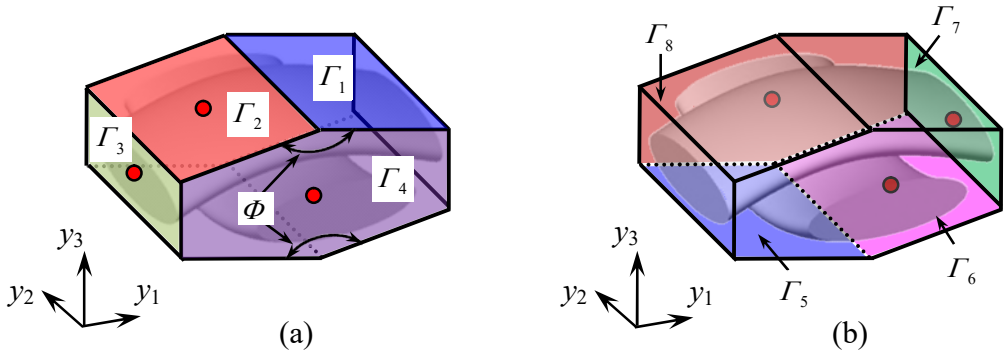

Fig. 3. Boundary facets of A; (a) Γ_1-Γ_4, (b) Γ_5-Γ_8.

where $\dot{(\cdot)}$ indicates the differentiation with respect to t, $F_{ij}(t)$ is the macroscopic deformation gradient, and $\dot{u}_i^{\#}(\boldsymbol{y},t)$ is the perturbed velocity. In the present nesting case, it is found from the cross-sectional view as illustrated in Fig. 4 that the microstructure possesses the periodicity in the α-direction. Thus, $\dot{u}_i^{\#}$ must be periodically distributed on Γ_1 and Γ_5. Further, one can find that the microstructure possesses the point-symmetries with respect to the centers of Γ_2, Γ_3, Γ_6 and Γ_7. In addition, such point-symmetries are satisfied with respect to the centers of Γ_4 and Γ_8. This suggests that $\dot{u}_i^{\#}$ on Γ_2 - Γ_4 and Γ_6 - Γ_8 should be point-symmetrically distributed with respect to these points (Fig. 4). It is clear that these periodicity and point-symmetries hold regarding the microscopic stress σ_{ij} and its rate $\dot{\sigma}_{ij}$.

2.2 Weak form of equilibrium of microscopic stress and its integral terms

The equilibrium of σ_{ij} in A can be expressed in a rate form as

$$\dot{\sigma}_{ij,j} = 0, \tag{2}$$

where $(\ )_{,j}$ denotes the differentiation with respect to y_j. The integration by parts and the divergence theorem allow Eq. (2) to be transformed to a weak form:

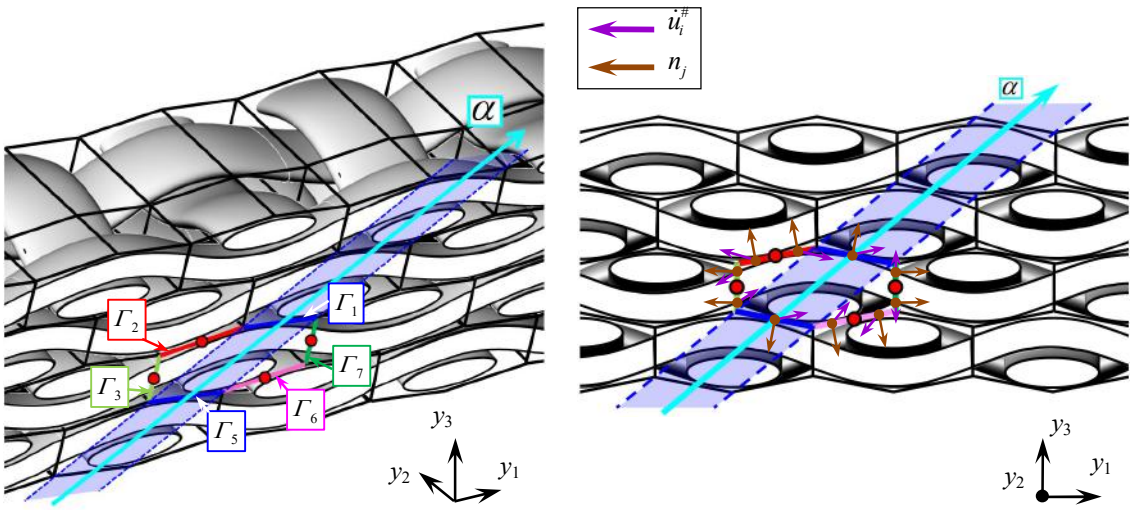

Fig. 4. Periodicity in the α-direction and point-symmetries with respect to the centersof Γ_2, Γ_3, Γ_6 and Γ_7,and perturbed velocity field $\dot{u}_i^{\#}$ and unit normal vector n_i on each boundary facet.

$$\int_A \dot{\sigma}_{ij} v_{i,j} dA - \int_\Gamma \dot{\sigma}_{ij} n_j v_i d\Gamma = 0, \tag{3}$$

where $v(\boldsymbol{y}, t)$ is an arbitrary variation of $\dot{u}_i^{\#}$, and n_j is the unit vector outward normal to Γ. It is noted that the boundary integral term in Eq. (3) can be expressed as

$$\int_\Gamma \dot{\sigma}_{ij} n_j v_i d\Gamma = \sum_{\alpha=1}^{8} \int_{\Gamma_\alpha} \dot{\sigma}_{ij} n_j v_i d\Gamma. \tag{4}$$

On Γ_1 and Γ_5, the periodicity of v_i and $\dot{\sigma}_{ij}$ is satisfied as already described in the previous subsection, whereas n_j takes the opposite directions on these boundary facets (Fig. 4), leading to the following relationship:

$$\int_{\Gamma_1} \dot{\sigma}_{ij} n_j v_i d\Gamma + \int_{\Gamma_5} \dot{\sigma}_{ij} n_j v_i d\Gamma = 0. \tag{5}$$

On Γ_2-Γ_4 and Γ_6-Γ_8, in contrast, the point-symmetries of v_i and $\dot{\sigma}_{ij}$ with respect to the centers of these facets are satisfied, whereas n_j keeps the same direction on the facets (Fig. 4). Thus, the boundary integral terms with respect to these areas become zero, and we obtain

$$\int_{\Gamma_\alpha} \dot{\sigma}_{ij} n_j v_i d\Gamma = 0, \ (\alpha = 2\text{-}4, 6\text{-}8). \tag{6}$$

From Eqs. (4), (5) and (6), the second term on the left side of Eq. (3) vanishes, which enables Eq. (3) to be rewritten as

$$\int_A \dot{\sigma}_{ij} v_{i,j} dA = 0. \tag{7}$$

2.3 Homogenization

The constitutive equation of constituents in A is expressed in a rate form as

$$\dot{\sigma}_{ij} = c_{ijkl} \left(\dot{\varepsilon}_{kl} - \beta_{kl} \right), \tag{8}$$

where c_{ijkl} and β_{kl} respectively denote the elastic stiffness and viscoplastic strain rate of the constituents, satisfying $c_{ijkl} = c_{jikl} = c_{ijlk} = c_{klij}$ and $\beta_{kl} = \beta_{lk}$, $\dot{\varepsilon}_{kl}$ indicates the microscopic strain rate. As already stated in the previous subsection, Eq. (7) has the same form as that of the original homogenization theory [10, 21, 22]. Therefore, according to the earlier works [21, 22], we can derive the following evolution equation of microscopic stress, and the relation between macroscopic stress rate $\dot{\Sigma}_{ij}$ and macroscopic strain rate $\dot{E}_{ij}$:

$$\dot{\sigma}_{ij} = c_{ijpq} \left(\delta_{pk} \delta_{ql} + \chi_{p,q}^{kl} \right) \dot{E}_{kl} - c_{ijkl} \left(\beta_{kl} - \varphi_{k,l} \right), \tag{9}$$

$$\dot{\Sigma}_{ij} = \left\langle c_{ijpq} \left(\delta_{pk} \delta_{ql} + \chi_{p,q}^{kl} \right) \right\rangle \dot{E}_{kl} - \left\langle c_{ijkl} \left(\beta_{kl} - \varphi_{k,l} \right) \right\rangle, \tag{10}$$

where δ_{ij} indicates the Kronecker's delta, $\langle \# \rangle$ stands for the volume average in A, i.e. $\langle \# \rangle = |A|^{-1} \int_A \# dA$, where $|A|$ signifies the volume of A. Moreover, χ_p^{kl} and φ_k are the functions to be determined by solving the following boundary value problems for A:

$$\int_A c_{ijpq} \chi_{p,q}^{kl} v_{i,j} dA = -\int_A c_{ijkl} v_{i,j} dA, \tag{11}$$

$$\int_A c_{ijpq}\varphi_{p,q}v_{i,j}dA = \int_A c_{ijkl}\beta_{kl}v_{i,j}dA, \tag{12}$$

In general, the boundary value problems (11) and (12) are solved numerically to find χ_p^{kl} and φ_k using the FEM. In this analysis, we impose the combination of the periodicity and point-symmetries already described in the previous subsections on χ_p^{kl} and φ_k as the boundary conditions. It should be noted that the present modeling method, including the boundary conditions, enables us to substantially reduce the analysis domain for plain-woven composites with nesting compared with the previous methods mentioned in the introduction, which is eminently suitable for nonlinear analysis accompanied by incremental computation.

3 ELASTIC-VISCOPLASTIC ANALYSIS OF PLAIN-WOVEN GFRP COMPOSITES WITH NESTING

3.1 Basic cell

To determine the geometry of the basic cell A, we performed SEM observation of cross-sections of the plain-woven GFRP composite. It is noted that, in the composite, nesting predominantly existed in the plane parallel to the warp-direction, whereas there was less nesting in the plane parallel to the weft-direction. We then measured the wavelength, shape, size and volume fraction of the fiber bundles, the fiber volume fraction in fiber bundles, and calculated their averaged values. Based on these observation results and averaged values, A with nesting in the y_3 - y_1 plane with 69% volume fraction of fiber bundles was defined using the aforementioned hexagonal prism cell (Fig. 5), and was divided into eight-node isoparametric elements (1888 elements, 2329 nodes). It is noteworthy that the number of elements, 1888, is much smaller than in the preceding studies dealing with plain-woven composites with nesting [5, 17].

3.2 Material properties

Fiber bundles were regarded as E-glass/epoxy unidirectional composites, and as transversely isotropic elastic materials. Their material properties were calculated using the homogenization theory on the assumption that the fiber volume fraction in fiber bundles was 72% in the accordance with the microscope observation, and that the fiber bundles had a hexagonal fiber array. The elastic constants of the E-glass fibers and epoxy used in the calculation were set as

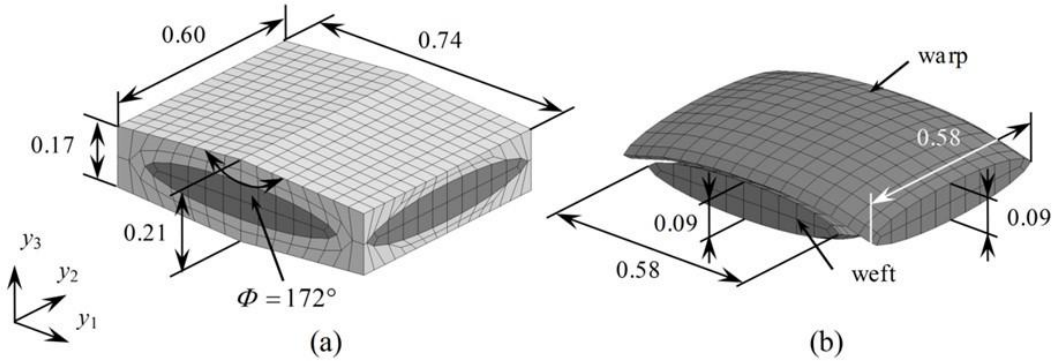

Fig. 5. Basic cell A of plain-woven GFRP laminates with nesting (1888 elements, 2329 nodes) with dimensions in mm; (a) full view, (b) fiber bundles (weft and warp) in A.

listed in Table 1. The epoxy matrix, on the other hand, was regarded as an isotropic elastic-viscoplastic material that obeyed the following constitutive equation [21-23]:

$$\dot{\varepsilon}_{ij} = \frac{1+\nu_{\mathrm{m}}}{E_{\mathrm{m}}}\dot{\sigma}_{ij} - \frac{\nu_{\mathrm{m}}}{E_{\mathrm{m}}}\dot{\sigma}_{kk}\delta_{ij} + \frac{3}{2}\dot{\varepsilon}_0^{\mathrm{p}}\left[\frac{\sigma_{\mathrm{eq}}}{g\left(\bar{\varepsilon}^{\mathrm{p}}\right)}\right]^n \frac{s_{ij}}{\sigma_{\mathrm{eq}}}, \tag{13}$$

where E_{m}, ν_{m} and n represent material constants, $g\left(\bar{\varepsilon}^{\mathrm{p}}\right)$ stands for the exponential hardening function (Voce's hardening function) depending on the equivalent viscoplastic strain $\bar{\varepsilon}^{\mathrm{p}}$ [19,24], $\dot{\varepsilon}_0^{\mathrm{p}}$ signifies the reference strain rate, s_{ij} denotes the deviatoric part of σ_{ij}, and $\sigma_{\mathrm{eq}} = \left[\left(3/2\right)s_{ij}s_{ij}\right]^{1/2}$. In this study, no failure of the fiber bundles and epoxy, and no delamination between the fiber bundles and epoxy were considered.

3.3 Loading condition

The plain-woven GFRP composites were subjected to a macroscopically uniaxial tensile load at a constant strain rate of 10^{-5} s^{-1} at room temperature. Five kinds of off-axis angles, i.e. $\theta = 0,\ 15,\ 30,\ 45$ and $90°$, were considered.

3.4 Results of analysis

Figure 6 shows the macroscopic stress-strain relations obtained from the present analysis and the tensile tests of the plain-woven GFRP composite with nesting subjected to the uniaxial

Table 1 Material constants.

E-glass	$E_{\mathrm{f}} = 80.0\times10^3$ $\quad \nu_{\mathrm{f}} = 0.22$
Epoxy	$E_{\mathrm{m}} = 3.5\times10^3$ $\quad \nu_{\mathrm{m}} = 0.35$ $\quad \dot{\varepsilon}_0^{\mathrm{p}} = 1.0\times10^{-5}$ $n = 30$ $\quad g(\bar{\varepsilon}^{\mathrm{p}}) = 19 - 18\times\exp(-190\times\bar{\varepsilon}^{\mathrm{p}})$

MPa (stress), mm/mm (strain), s (time)

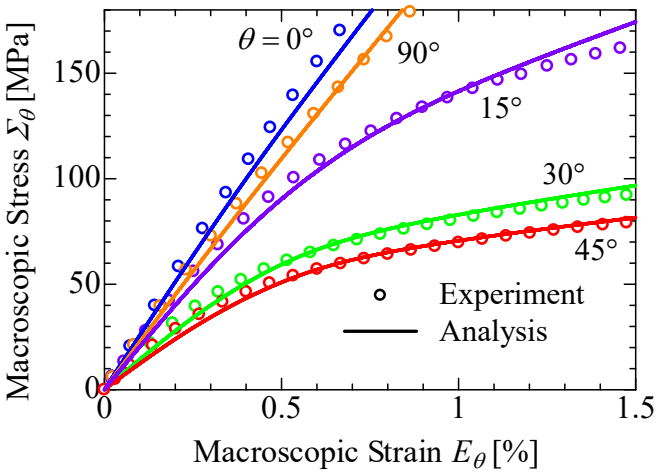

Fig. 6. Macroscopic stress-strain relations of plain-woven GFRP laminate with nesting at $\theta = 0,\ 15,\ 30,\ 45$ and $90°$ at $\dot{E}_\theta = 1.0\times10^{-5}$ s^{-1}.

tension with $\theta = 0,\ 15,\ 30,\ 45$ and $90°$. In the figure, the analysis and the experimental results are respectively indicated by the solid lines and open circles. As seen from the experimental results in Fig. 6, the macroscopic stress-strain relations markedly depend on θ, indicating that the plain-woven GFRP composite possesses remarkable elastic-viscoplastic anisotropy [13-15]. Comparing such experimental data with the analysis results, it is found that the present modeling method is successful in predicting the macroscopic behavior of the plain-woven GFRP composite.

4 CONCLUSIONS

- The present method enabled us to substantially reduce the analysis domain for the homogenization analysis of plain-woven composites with nesting compared with the previous methods. This is eminently suitable for nonlinear analysis accompanied by incremental computation including the elastic-viscoplastic analysis performed in this study.
- High volume fraction of fiber bundles (69% in the present case) was achieved using the present modeling method. This could not be attained if conventional cuboid cells were employed. The present method therefore becomes significantly effective, especially in the case of the high volume fraction of fiber bundles caused by nesting as seen in the plain-woven GFRP composite dealt with in this study.
- Comparison between the analysis and the experimental results revealed that the present method was capable of accurately predicting the in-plane macroscopic elastic-viscoplastic behavior of the plain-woven GFRP composite with nesting.

ACKNOWLEDGMENTS

This presentation is based on results obtained from a project (P16010) commissioned by the New Energy and Industrial Technology Development Organization of Japan (NEDO). The presenter, G. Kubo, is grateful to the International Association for Computational Mechanics (IACM) for providing the IACM Scholarship covering his registration fee to participate in the 13th World Congress on Computational Mechanics (WCCM XIII) and the 2nd PanAmerican Congress on Computational Mechanics (PANACM II).

A Control Volume Finite Element Approach for Modeling Molten Corium Spreading and Solidification

Alec Kucala*, Rekha Rao**, Lindsay Erickson***, David Noble****

*Sandia National Laboratories, **Sandia National Laboratories, ***Sandia National Laboratories, ****Sandia National Laboratories

ABSTRACT

When the core is breached during a severe nuclear accident, a molten mixture of nuclear fuel, cladding, and structural supports is discharged from the reactor vessel, which is often referred to as “corium”. This scenario poses a difficult modeling problem due to the presence of large Peclet and Reynolds numbers, whereby the standard Galerkin based finite-element method (GFEM) technique is inadequate in suppressing the spurious oscillations in the mass, momentum, and energy equations. To address these oscillations, we implement a control volume finite element method (CVFEM) which allows for an upwinding treatment of the advection terms in the momentum and energy equations. Modeling the spreading of molten corium also requires a robust and accurate representation of the corium/air interface in two- and three-dimensions. To accomplish this, the conformal decomposition finite element method (CDFEM) is utilized to dynamically discretize the moving interface, allowing for the direct application of boundary conditions at the melt/air interface, such as surface tension and radiative energy transfer to the surrounding air. This CVFEM-CDFEM approach is used to model the spreading of molten corium in two- and three-dimensions, where the solidification of the melt is modeled using a temperature-dependent viscosity model. First, it is shown that the CVFEM technique is able to suppress spurious oscillations that GFEM cannot, where upwinding is introduced in the advection terms of the level set, momentum and energy equations. Our model is then compared directly with the FARO L26 corium spreading experiments and with previous numerical simulations in two- and three-dimensions. In these comparisons, good agreement is obtained with the evolution of the time-dependent corium spreading front.

Evaluation of Vehicle Aerodynamic Performance with Lane Change and Passing Using CFD and MBD

Toshifumi Kudo*

*Altair Engineering

ABSTRACT

Evaluation of aerodynamic performance using Wind Tunnels and CFD analysis conducted in each OEMs has great contribution to improve fuel consumption and performance of automobiles. The CFD has become more detail and has been able to solve a bigger scale problem in every year, a deviation between experimental and analysis results almost negligible and it is an effective tool for design and development process. However, is it enough to perform only Wind Tunnel experiments and CFD? Cross wind and air flow coming from various kind of other vehicles has a significant impact in actual driving. Furthermore, a vehicle posture changes due to the influence of air flow. That flow changes as the change of the vehicle attitude. Thus, in fact it is more complicated and fundamentally different from Wind Tunnel experiments. In principle, in order to better understand a physical phenomenon occurred, it is important to grasp a complex physical phenomenon rather than only solve a particular phenomenon. However, since governing equations vary in every physical phenomenon, it is important to couple each one. For this reason, this research aims to carry out analysis in a real condition and thus, the coupled analysis of mechanical and fluid is performed. As an example, we assume the following situation. Two cars are moving while receiving crosswinds, the latter vehicle changes its lanes and passing thru the front run vehicle. The vehicle has a steering and suspension system and the vehicle attitude changes as the change of the wind or lane. In order to carry out the simulation with taking all these conditions into consideration, the suspension and steering mechanism are included in Driver model of Multibody Dynamics analysis(MBD). It is then required to simulate the fluid flowing around the vehicle and to solve them simultaneously. In MBD we calculate displacement of the tire, steering, vehicle attitude, and store the displacement results to the CFD side. The CFD solver calculates the air flow using the calculated displacements obtained by MBD. At the end, force and moment are applied to the vehicle and we alternately performs this analysis through Multibody Dynamics analysis. Based on this simulation, it is now possible to estimate behavior of the vehicle which is not actually obtained by Wind Tunnel experiments including the influence of air flow from side wind, other vehicles. It is expected to be useful method in the product development process with higher accuracy and higher efficiency.

Key words: Non-uniform torsion; Vlasov's theory of torsion; Benscoter-related theory of torsion; Identification of stiffness parameters; SAFE

Abstract. All but axi-symmetric cross-sections warp during torsion, i.e. the cross-section deforms axially, and a warping or non-uniform theory of torsion has to be applied. Since the corresponding influence is severe in thin-walled open profiles much of the literature only covers thin-walled cross sections by Vlasov's theory of torsion. In this paper the classical Vlasov - theory is generalized to end up in a model similar to Bescoter's theory which is shown to be more accurate. A procedure to evaluate all arising stiffness quantities in arbitrarily shaped cross-sections accompanied with arbitrarily distributed constitutive parameters is proposed based on a reference beam problem in connection with semi-analytical finite elements. For the proposed theories of warping torsion effective finite beam elements are derived, and challenging benchmark-problems show the accuracy and the efficiency of the proposed formulations.

1 INTRODUCTION

Beam structures made of a Functionally Graded Materials (FGMs) show location dependent material parameters throughout their arbitrarily shaped cross-section. The load case of torsion introduces warping of the cross-section and a non-uniform theory of torsion has to be applied to achieve accurate solutions using one-dimensional finite elements. Starting with a suitable kinematic assumption where the cross-section rotates rigidly in its projection plane pivoting at the shear or drill center, the axial motion of a generic point is quantified based on an unknown warping function (depending

on the cross-section coordinates) multiplied with an axial field quantifying the amount of warping. The well-known and frequently applied Vlasov's theory of torsion [1] uses the first derivative of torsion angle $\varphi_x^{'}$ to quantify warping axially. This leads to two independent stiffness quantities (torsion stiffness and warping stiffness) which have to be identified in connection with one fourth order ordinary differential equation (ODE).
Alternatively, if the axial distribution of warping may be related to a yet unknown independent field rather than to the rate of twist, we end up with two coupled second order ODEs with four stiffness quantities. Such a calculation strategy is similar to the theory of Benscoter [3]. It can be shown by example that this theory leads to more accurate results compared to Vlasov's theory, especially for thick shafts. While the analytical evaluations regarding a set of two coupled ODEs are somewhat more involved very efficient finite beam elements can be derived based on linear shape functions. The evaluations of the related stiffness quantities can be carried out using a reference beam problem of arbitrary length in connection with three dimensional elasticity solutions where semi-analytical finite elements (SAFE) are applied. Due to SAFE and a specialized load case for the reference problem a true dimensional reduction is achieved and stress distributions, relevant cross-section parameters and stiffness quantities are accessible based on discretization of the cross-section only [2].

2 THEORY OF NON-UNIFORM TORSION

Under torsion any cross-section rotates about a specific location[1] with respect to the axial direction. The torsional angle $\varphi_x(x)$ is found from a differential equation which is derived from suitable kinematic hypotheses, the strain displacement relations and the constitutive equations. The derivation is based on the principle of virtual work which is well suited to generate two-noded finite elements. If a cross-section warps during torsional loading the points of the cross-section undergo axial displacements u_x. The displacement field $u_x(x, y, z)$ at a specific cross-section x is assumed in a multiplicative form,

$$u_x(x, y, z) = F(x)\omega(y, z), \tag{1}$$

where $\omega(y, z)$ is the warping function. Figure 1 depicts the kinematics of torsion problems: There, we model an arbitrary cross-section with arbitrary material distributions in the y_m-z_m, where the elastic center C (decoupling axial from bending deformations) and the shear center S (congruent with the drill center) is known (see [2]). The origin of the beam's coordinate system is located at C and the y- and z-axis is directed into the cross-sections principal directions. Any other orientation of the corresponding coordinate system might be possible without any further complexities for torsional loading, however, in light of shear force bending such an orientation is typically suggested. We then assume that the cross-section rotates rigidly about the shear (or drill) center S in terms of the torsional angle $\varphi_x(x)$ and a generic point of the cross-section undergoes axial deformations,

[1] This specific location is called the drill center S and is congruent with the shear center of the cross-section which decouples torsion from shear force bending.

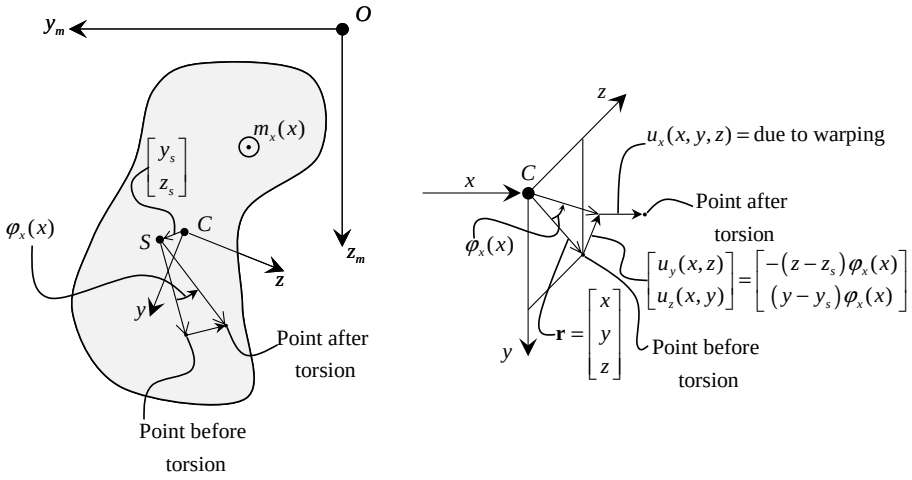

Figure 1: Kinematics of torsion

i.e. the cross-section is assumed to be rigid in its projection plane (any distortional deformations are neglected) but warpes axially. According to the assumption (1) Vlasov assumes $F(x) = \varphi_x^{'}(x)$ while the Benscoter theory leaves $F(x)$ to be determined. Hence, we have,

$$\text{Vlasov: } u_x(x,y,z) = \omega(y,z)\varphi_x^{'}(x), \tag{2}$$

$$\text{Benscoter: } u_x(x,y,z) = \omega(y,z)F(x). \tag{3}$$

2.1 Vlasov's theory of torsion

According to Fig. 1 a generic point of the cross-section at x with the position vector $\mathbf{r} = \begin{bmatrix} x & y & z \end{bmatrix}^T$ displaces in the cross-section according to

$$u_y(x,z) = -(z - z_s)\,\varphi_x(x), \tag{4}$$

$$u_z(x,y) = (y - y_s)\,\varphi_x(x), \tag{5}$$

where $\varphi_x(x)$ denotes the torsional angle and displaces out of that plane according to (2). Based on the above described kinematics we evaluate the strain fields according to the strain displacement relations,

$$\epsilon_{xx}(x,y,z) = \frac{\partial u_x(x,y,z)}{\partial x} = \omega(y,z)\varphi_x^{''}(x), \tag{6}$$

$$\epsilon_{yy} = \frac{\partial u_y(x,z)}{\partial y} = 0,\ \epsilon_{zz} = \frac{\partial u_z(x,y)}{\partial z} = 0, \tag{7}$$

$$\gamma_{xy}(x,y,z) = \frac{\partial u_x(x,y,z)}{\partial y} + \frac{\partial u_y(x,z)}{\partial x} =$$

$$= \left(\frac{\partial \omega(y,z)}{\partial y} - (z - z_s) \right) \varphi_x^{'}(x) = (\omega_{,y} - (z - z_s))\, \varphi_x^{'}(x), \tag{8}$$

$$\gamma_{xz}(x,y,z) = \frac{\partial u_x(x,y,z)}{\partial z} + \frac{\partial u_z(x,y)}{\partial x} =$$

$$= \left(\frac{\partial \omega(y,z)}{\partial z} + (y - y_s) \right) \varphi_x^{'}(x) = (\omega_{,z} + (y - y_s))\, \varphi_x^{'}(x), \tag{9}$$

$$\gamma_{yz} = \frac{\partial u_y(x,z)}{\partial z} + \frac{\partial u_z(x,y)}{\partial y} = -\varphi_x(x) + \varphi_x(x) = 0, \tag{10}$$

and the non-vanishing stress fields are found according to the constitutive relations,

$$\sigma_{xx}(x,y,z) = E(y,z)\epsilon_{xx}(x,y,z) = E(y,z)\omega(y,z)\varphi_x^{''}(x), \tag{11}$$

$$\tau_{xy}(x,y,z) = G(y,z)\gamma_{xy}(x,y,z) = G(y,z)\,(\omega_{,y} - (z - z_s))\,\varphi_x^{'}(x), \tag{12}$$

$$\tau_{xz}(x,y,z) = G(y,z)\gamma_{xz}(x,y,z) = G(y,z)\,(\omega_{,z} + (y - y_s))\,\varphi_x^{'}(x), \tag{13}$$

where isotropy at each material point is understood (Young's modulus E and shear modulus G). Using the principle of virtual work $\delta W_a + \delta W_i = 0$ with prescribed kinematic boundary conditions at both beam ends ($\delta\varphi_x(0) = \delta\varphi_x(l) = \delta\varphi_x^{'}(0) = \delta\varphi_x^{'}(l) = 0$) we have an external load due to a line moment $m_x(x)$ $[N]$,

$$\int_l m_x(x)\delta\varphi_x(x)dx - \int_V \sigma_{xx}\delta\epsilon_{xx}dV - \int_V \tau_{xy}\delta\gamma_{xy}dV - \int_V \tau_{xz}\delta\gamma_{xz}dV = 0, \tag{14}$$

and further,

$$\int_l m_x(x)\delta\varphi_x(x)dx - \int_l \underbrace{\int_A E(y,z)\omega^2(y,z)dA}_{=E_TC_\omega}\, \varphi_x^{''}(x)\delta\varphi_x^{''}(x)dx -$$

$$- \int_l \underbrace{\int_A G(y,z)\left[(\omega_{,y} - (z - z_s))^2 + (\omega_{,z} + (y - y_s))^2\right] dA}_{=G_TI_T}\, \varphi_x^{'}(x)\delta\varphi_x^{'}(x)dx = 0, \tag{15}$$

where warping stiffness E_TC_ω $[Nm^4]$ and the torsional stiffness G_TI_T $[Nm^2]$ are defined. Applying integration by parts,

$$\int_l m_x(x)\delta\varphi_x(x)dx - \int_l E_TC_\omega\varphi_x^{''''}(x)\delta\varphi_x(x)dx + \int_l G_TI_T\varphi_x^{''}(x)\delta\varphi_x(x)dx =$$

$$= \int_l \left(m_x(x) - E_T C_\omega \varphi_x^{''''}(x) + G_T I_T \varphi_x^{''}(x) \right) \delta\varphi_x(x) dx = 0, \tag{16}$$

delivers for arbitrary variations of the torsional angle the describing differential equation for warping torsion,

$$E_T C_\omega \varphi_x^{''''}(x) - G_T I_T \varphi_x^{''}(x) = m_x(x). \tag{17}$$

2.2 A Benscoter related theory of torsion

In Benscoter's theory [3] the kinematics are assumed according to (1)

$$u_x(x, y, z) = \omega(y, z) F(x), \tag{18}$$

and

$$u_y(x, z) = -(z - z_s)\, \varphi_x(x),\ u_z(x, y) = (y - y_s)\, \varphi_x(x), \tag{19}$$

where axial warping deformations vary according to an unknown function $F(x)$ along the beam's axis. This approach is also discussed in [4]. The non-vanishing strain fields read,

$$\epsilon_{xx}(x, y, z) = \frac{\partial u_x(x, y, z)}{\partial x} = \omega(y, z) F^{'}(x), \tag{20}$$

$$\gamma_{xy}(x, y, z) = \frac{\partial u_x(x, y, z)}{\partial y} + \frac{\partial u_y(x, z)}{\partial x} = \omega_{,y} F(x) - (z - z_s)\, \varphi_x^{'}(x), \tag{21}$$

$$\gamma_{xz}(x, y, z) = \frac{\partial u_x(x, y, z)}{\partial z} + \frac{\partial u_z(x, y)}{\partial x} = \omega_{,z} F(x) + (y - y_s)\, \varphi_x^{'}(x), \tag{22}$$

and the stress fields are

$$\sigma_{xx}(x, y, z) = E(y, z) \epsilon_{xx}(x, y, z) = E(y, z) \omega(y, z) F^{'}(x), \tag{23}$$

$$\tau_{xy}(x, y, z) = G(y, z) \gamma_{xy}(x, y, z) = G(y, z) \left(\omega_{,y} F(x) - (z - z_s)\, \varphi_x^{'}(x) \right), \tag{24}$$

$$\tau_{xz}(x, y, z) = G(y, z) \gamma_{xz}(x, y, z) = G(y, z) \left(\omega_{,z} F(x) + (y - y_s)\, \varphi_x^{'}(x) \right). \tag{25}$$

The principle of virtual work with the kinematic variables φ_x and F gives for prescribed kinematic variables at both beam ends ($\delta\varphi_x(0) = \delta\varphi_x(l) = \delta F(0) = \delta F(l) = 0$),

$$\int_l m_x(x) \delta\varphi_x(x) dx - \int_l \int_A E(y, z) \omega^2(y, z) dA\, F^{'}(x) \delta F^{'}(x) dx -$$

$$- \int_l \int_A G(y, z) \omega_{,y}^2 dA\, F(x) \delta F(x) dx +$$

$$+\int_l\int_A G(y,z)\omega_{,y}\left(z-z_s\right)dA\,\left(F(x)\delta\varphi_x^{'}(x)+\varphi_x^{'}(x)\delta F(x)\right)dx-$$

$$-\int_l\int_A G(y,z)\left(z-z_s\right)^2 dA\varphi_x^{'}(x)\delta\varphi_x^{'}(x)dx-\int_l\int_A G(y,z)\omega_{,z}^2 dA\,F(x)\delta F(x)dx-$$

$$-\int_l\int_A G(y,z)\omega_{,z}\left(y-y_s\right)dA\,\left(F(x)\delta\varphi_x^{'}(x)+\varphi_x^{'}(x)\delta F(x)\right)dx-$$

$$-\int_l\int_A G(y,z)\left(y-y_s\right)^2 dA\varphi_x^{'}(x)\delta\varphi_x^{'}(x)dx=0, \tag{26}$$

which can be rewritten as,

$$\int_l m_x(x)\delta\varphi_x(x)dx-\int_l\underbrace{\int_A E(y,z)\omega^2(y,z)dA}_{=E_TC_\omega}\,F^{'}(x)\delta F^{'}(x)dx-$$

$$-\int_l\underbrace{\int_A G(y,z)\left(\omega_{,y}^2+\omega_{,z}^2\right)dA}_{=K_1}\,F(x)\delta F(x)dx-$$

$$-\int_l\underbrace{\int_A G(y,z)\left(\left(y-y_s\right)\omega_{,z}-\left(z-z_s\right)\omega_{,y}\right)dA}_{=K_2}\left(F(x)\delta\varphi_x^{'}(x)+\varphi_x^{'}(x)\delta F(x)\right)dx-$$

$$-\int_l\underbrace{\int_A G(y,z)\left(\left(y-y_s\right)^2+\left(z-z_s\right)^2\right)dA}_{=K_3}\,\varphi_x^{'}(x)\delta\varphi_x^{'}(x)dx=0, \tag{27}$$

defining four stiffness quantities, E_TC_ω and K_i for $i=1,2,3$. Note, that (27) coincides with (15) if $F(x)=\varphi_x^{'}(x)$ is and

$$G_TI_T=K_1+2K_2+K_3. \tag{28}$$

Integrating (27) by parts yields,

$$\int_l m_x(x)\delta\varphi_x(x)dx+\int_l E_TC_\omega\,F^{''}(x)\delta F(x)dx-\int_l K_1\,F(x)\delta F(x)dx-$$

$$-\int_l K_2\left(-F^{'}(x)\delta\varphi_x(x)+\varphi_x^{'}(x)\delta F(x)\right)dx+\int_l K_3\varphi_x^{''}(x)\delta\varphi_x(x)dx=0, \tag{29}$$

giving the Euler-Lagrange equations representing a system of coupled differential equations[2],

$$m_x(x) + K_2 F^{'}(x) + K_3 \varphi_x^{''}(x) = 0, \tag{30}$$

$$E_T C_\omega \, F^{''}(x) - K_1 \, F(x) - K_2 \varphi_x^{'}(x) = 0. \tag{31}$$

Note that the strong form (30) (31) cannot be converted into the formulation (15) anymore and different results are expected.

3 EVALUATION OF STIFFNESS QUANTITIES AND STRESS DISTRIBUTIONS BASED ON SAFE

The identification of relevant stiffness quantities (warping stiffness $E_T C_\omega$ and torsional stiffness $G_T I_T$ (15) accompanied with K_i for $i = 1, 2, 3$ (27)) is performed on a reference beam problem (modeled in the y_m-z_m coordinate system) of arbitrary length l_{RB} which is analyzed by a three-dimensional elasticity formulation and the procedures discussed in [2]. The beam is assumed to rest on fork supports, i.e. $\varphi_x = \sigma_{xx} = 0$ at both beam ends. Transverse volume forces f_i for $i = y_m, z_m$ are applied (varying as a sine function with $\alpha = {}^{n\pi}/_{l_{RB}}$, $n = 1$)

$$f_{y_m} = f_{y_{m0}} \sin(\alpha x_m) = (b_{y0} + b_{yy} y_m + b_{yz} z_m) \, E(y_m, z_m) \sin(\alpha x_m), \tag{32}$$

$$f_{z_m} = f_{z_{m0}} \sin(\alpha x_m) = (b_{z0} + b_{zy} y_m + b_{zz} z_m) \, E(y_m, z_m) \sin(\alpha x_m), \tag{33}$$

which are scaled by the location dependent Young's modulus $E(y_m, z_m)$. The constant quantities $b_{uv} \neq b_{vu}$ with $u = y, z$ and $v = 0, y, z$ are unknowns at this stage, however, they can be identified by requiring that the reference beam problem has to react as shaft. Hence, we require

$$q_{y_m 0} = \int_A f_{y_m 0} dA = 0 \tag{34}$$

$$q_{z_m 0} = \int_A f_{z_m 0} dA = 0 \tag{35}$$

$$m_{x0} = \int_A (y_m f_{z_m 0} - z_m f_{y_m 0}) \, dA = 1 \tag{36}$$

We thus have three equations with six unknown parameters which can be solved by the Moore-Penrose pseudo-inverse. The mean torsional angle amplitude can be evaluated,

$$\overline{\varphi}_x = b_{y0} \overline{\varphi}_x^{b_{z0}} + b_{yy} \overline{\varphi}_x^{b_{zy}} + b_{yz} \overline{\varphi}_x^{b_{zz}} + b_{z0} \overline{\varphi}_x^{b_{z0}} + b_{zy} \overline{\varphi}_x^{b_{zy}} + b_{zz} \overline{\varphi}_x^{b_{zz}}, \tag{37}$$

[2]This formulation introduces four stiffness parameters, but it can be shown that $K_1 = -K_2$ if the same warping function ω is used for either Vlasov's theory or the Benscoter-related theory.

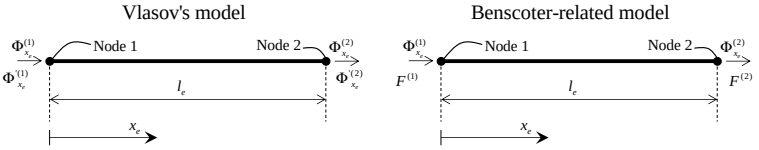

Figure 2: Two-noded beam finite element for Vlasov's and Benscoter's theory of torsion

where $\overline{\varphi}_x^{b_{uv}}$ denote the mean value of torsional angle with respect to the cross-section's area evaluated from the reference beam problem due to the application of b_{uv} only (see [2] for additional details). According to Vlasov's theory the out of plane motion,

$$u_x(x, y_m, z_m) = \omega(y_m, z_m)\varphi_x^{'}(x), \tag{38}$$

is proportional to $\varphi_x^{'}(x)$ and we find the nodal warping amplitudes $\boldsymbol{\omega}$ as

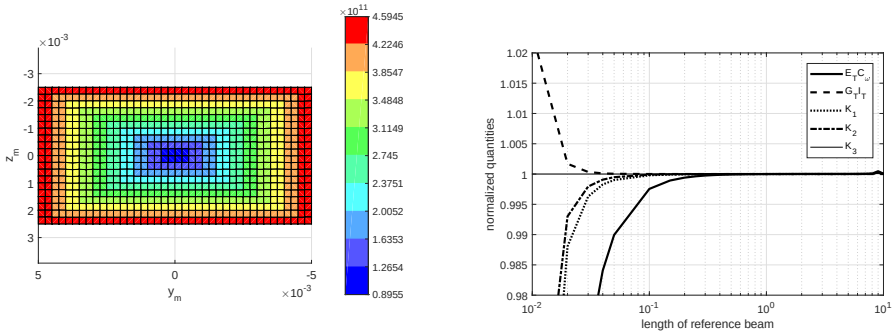
$$\boldsymbol{\omega} = \frac{\mathbf{U}_x}{\alpha\overline{\varphi}_x} = \frac{\sum_{u=y}^{z}\sum_{v=0}^{z} b_{uv}\mathbf{U}_x^{b_{uv}}}{\alpha\overline{\varphi}_x}. \tag{39}$$

Once the warping distribution is at hand all stiffness properties can be evaluated. As a side product axial and shear stress distributions due to a unity torsional moment and unity bimoment $M_\omega = \int_A \omega\sigma_{xx}dA$ are found without any additional effort. The reference beam problem is analyzed by semi-analytical finite elements (SAFE) (see [2, 5]) where only the cross-section of the beam has to be discretized since axial variations are assumed to be analytical functions. The only remaining free parameter of the reference problem is the length of the reference beam l_{RB}, where it can be shown that accurate solutions can be achieved for $10r < l_{RB} < 500r$, where r denotes a characteristic geometrical dimension of the actual cross-section. For $l_{RB} < 10r$ beam theory is no longer accurate since cross-sectional distortions become important. For lengths $l_{RB} > 500r$ some numerical problems regarding SAFE start to emanate.

4 FINITE ELEMENT FORMULATIONS

In this section we present very briefly a two-noded beam finite element of length l_e for both theories (see Fig. 2). The nodal degrees of freedom are the torsional angle Φ_x and either $\Phi_x^{'}$ or F. We use polynomial shape functions (cubic for Vlasov's theory and linear for Benscoter's model). This yields to the following equations
Vlasov:

$$\left\{\frac{E_T C_\omega}{{l_e}^3}\begin{bmatrix} 12 & 6\,l_e & -12 & 6\,l_e \\ 6\,l_e & 4\,{l_e}^2 & -6\,l_e & 2\,{l_e}^2 \\ -12 & -6\,l_e & 12 & -6\,l_e \\ 6\,l_e & 2\,{l_e}^2 & -6\,l_e & 4\,{l_e}^2 \end{bmatrix} + \frac{G_T I_T}{30\,l_e}\begin{bmatrix} 36 & 3\,l_e & -36 & 3\,l_e \\ 3\,l_e & 4\,{l_e}^2 & -3\,l_e & -{l_e}^2 \\ -36 & -3\,l_e & 36 & -3\,l_e \\ 3\,l_e & -{l_e}^2 & -3\,l_e & 4\,{l_e}^2 \end{bmatrix}\right\}\begin{bmatrix} \Phi_{x_e}^{(1)} \\ \Phi_{x_e}^{'(1)} \\ \Phi_{x_e}^{(2)} \\ \Phi_{x_e}^{'(2)} \end{bmatrix} = \frac{m_{x0}l_e}{2}\begin{bmatrix} 1 \\ {l_e}/6 \\ 1 \\ -{l_e}/6 \end{bmatrix}. \tag{40}$$



(a) Distribution of Young's modulus in rectangular FGM cross-section

(b) Convergence characteristic for either parameters with respect to large variations of RB-lengths

Figure 3: Rectangular FGM cross-section

Benscoter:

$$\begin{bmatrix} \frac{K_3}{l_e} & -\frac{K_2}{2} & -\frac{K_3}{l_e} & -\frac{K_2}{2} \\ -\frac{K_2}{2} & \frac{K_1\, l_e}{\chi_1} + \frac{E_T C_\omega}{l_e} & \frac{K_2}{2} & \frac{K_1\, l_e}{\chi_2} - \frac{E_T C_\omega}{l_e} \\ -\frac{K_3}{l_e} & \frac{K_2}{2} & \frac{K_3}{l_e} & \frac{K_2}{2} \\ -\frac{K_2}{2} & \frac{K_1\, l_e}{\chi_2} - \frac{E_T C_\omega}{l_e} & \frac{K_2}{2} & \frac{K_1\, l_e}{\chi_1} + \frac{E_T C_\omega}{l_e} \end{bmatrix} \begin{bmatrix} \Phi_{x_e}^{(1)} \\ F^{(1)} \\ \Phi_{x_e}^{(2)} \\ F^{(1)} \end{bmatrix} = \frac{m_{x0} l_e}{2} \begin{bmatrix} 1 \\ 0 \\ 1 \\ 0 \end{bmatrix} \tag{41}$$

The constants χ_1 and χ_2 in equation (40) depend on the order of integration,

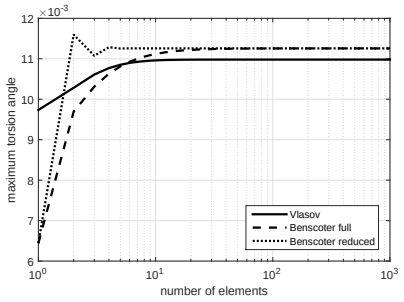
$$\text{Full integration (2 Gauss-points)}: \ \chi_1 = 3\,, \ \chi_2 = 6, \tag{42}$$

$$\text{Reduced integration (1 Gauss-point)}: \ \chi_1 = \chi_2 = 4. \tag{43}$$

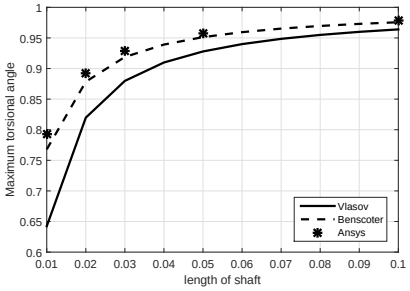
It can be shown by example that the selectively reduced formulation converges much faster since locking effects are resolved.

5 EXAMPLE, RESULTS AND DISCUSSION

For sake of space only one example can be described here where we consider a rectangular cross-section (height $h = 5 \cdot 10^{-3}$, width $w = 10 \cdot 10^{-3}$) which is made from pure aluminum (Al6061-TO, $E = 69$GPa, $\nu = 0.33$) in the core and pure titancarbid (TiC, $E = 480$GPa, $\nu = 0.33$) at the outer surfaces. Due to Murin et al. [8] the variation of the material properties is assumed to be linear in both transverse directions (see Fig. 3a where ten layers are used to approximate the continuous distribution). The mesh density defines the model of the continuous variation of Young's modulus, i.e. the continuous variation is approximated by layers of one element horizontally and two elements vertically. It is shown in [8] that the application of ten layers delivers good accuracy regarding the stiffness quantities which are evaluated using a completely different procedure compared to



(a) Convergence of the herein proposed elements for torsion $l = 0.05$, prevented warping at $x = l$, $M_x = 10$



(b) Maximum torsion angle at the location of the load (warping is prevented at $x = l$) for different shaft lengths ($M_x = \frac{G_T I_T}{l}$)

Figure 4: Results in a clamped shaft

the present one. The stiffness quantities are found using the proposed procedure and $l_{RB} = 1$ as the length of the reference beam ($E_T C_\omega = 1.3727e-04$, $G_T I_T = 42.2540$, $K_1 = 35.3680$, $K_2 = -35.3681$ and $K_3 = 77.6221$). The convergence characteristic over a wide range of reference beam lengths is shown in Fig. 3b which indicates a relative error of less than two percent within an interval of $0.04 < l_{RB} < 5$ (all quantities are normalized to the corresponding ones using $l_{RB} = 1$).

Using these stiffness parameters we analyze the torsional behavior of a shaft of length l which is clamped at $x = 0$ ($\varphi_x = 0$ and $u_x = 0$) and loaded with a torsion moment M_x at $x = l$. Reference solutions are found using Ansys (regular mesh of linear brick elements with enhanced strain formulation, edge length: $0.25 \cdot 10^{-3}$) where the load is applied using a rigid contact with pilot (RBE2 element) and a concentrated torsional moment on the pilot node. The application of the load using an RBE2 element causes restrained warping at $x = l$. The corresponding outcome indicates good agreement of both theories of torsion compared to Ansys. Nevertheless, Vlasov's theory of torsion delivers a relative error of three percent while Benscoter's theory leads to 0.6 percent relative error for $l = 0.1$ and $l = 0.05$. This indicates that Benscoter's theory is slightly more predictive in that problem. The convergence characteristic of the proposed finite beam elements regarding a shaft length of $l = 0.05$ for Vlasov's cubic element, Benscoter's fully integrated linear element and Benscoter's reduced integrated linear element are shown in Fig. 4a, where accurate results are indicated for more than ten elements (Benscoter's fully integrated linear element shows the worst convergence characteristic indicating two percent error for ten elements). The maximum torsional angle at the location of the load due to $M_x = \frac{G_T I_T}{l}$ is shown in Fig. 4b for different shaft length and compared to Ansys. As expected all results converge to $\varphi_x^{max} = 1$ for rather long shafts where warping is not important anymore (St. Venant problem), however, the system becomes stiffer in case of short shafts due to non-negligible warping effects. It turns out that the results due to the Benscoter-related model are much more accurate compared to Vlasov's model in the problem of short shafts.

Phase Field Modeling of Cracks in Heterogeneous Materials

Charlotte Kuhn*, Ralf Müller**

*University of Kaiserslautern, **University of Kaiserslautern

ABSTRACT

One of the reasons why the phase field approach has become very popular for modeling fracture processes is that therein the entire evolution of fracture follows from energetic principles without the need for different criteria for crack initiation, nucleation, kinking or branching. Furthermore, these models allow for a straightforward numerical implementation with standard finite elements, since displacement jumps and stress singularities are avoided in these models. Consequently, phase field fracture models are now also used to model and simulate fracture of heterogeneous materials such as composites, where cracks may be arrested, deflected or bifurcated at interfaces between the different components of the composite material, resulting in complicated crack patterns. The crack propagation is not only controlled by the elastic and fracture properties of the bulk phases of the material but also by the properties of the interfaces in between. Thus, it is crucial to take these interface properties into account, and there are conceptually different approaches on how to integrate them into phase field fracture models. In [1] interfaces are modeled as zones of finite width with appropriately adjusted fracture parameters. Contrary, a combination with a cohesive type of modeling interface fracture is proposed in [2]. Another approach, which makes use of a new energetic formulation mixing bulk and cohesive surface energies, is proposed in [3]. In this work, interfaces are equipped with a fracture energy corresponding to the phase field fracture energy of the bulk phases in order to model the interface fracture properties. In the finite element implementation, the interfaces are modeled by means of surface elements without introducing additional degrees of freedom. The convergence behavior of the proposed model with respect to the sharp interface limit of the phase field fracture model as well as energy release rates during crack propagation are analyzed in numerical studies in order to verify the model. Augmented Total-FETI Algorithm for Computationally Efficient Micromechanical Analysis of a Representative Volume Element

Nagesh Kulkarni*, BP Gautham**, Salil Kulkarni***

*TCS Research, Tata Consultancy Services Ltd. India, presently pursuing PhD at Mechanical Engineering Dept. IIT Bombay, India, **TCS Research, Tata Consultancy Services Ltd., India, ***Mechanical Engineering Dept., IIT Bombay, India

ABSTRACT

Representative Volume Element (RVE) is the smallest material volume that represents the material in terms of effective properties of interest. Analysis of a RVE is typically carried out to obtain response of material as a function of its underlying microstructure for a given load path. Periodic boundary conditions, which simulate the effect of embedding the RVE in a spatially infinite periodic structure, are commonly used in the analysis. They do not necessarily provide a good estimate of the effective properties if the size of the RVE is not very small as compared to the overall dimensions of the structure. The aim of this work is to develop an accurate and computationally efficient algorithm that effectively utilizes the principle of domain decomposition methods in a novel and natural way for estimating the effective properties of a periodic microstructure which is spatially finite in extent. The microstructure is assumed to be composed of a basic unit called cell which is spatially repeating. Instead of assuming the cell to be a RVE and applying periodic boundary conditions, the RVE is assumed to be composed of multiple identical cells glued together. It is then subjected to either uniform traction or uniform displacement boundary conditions as these are more representative of the actual boundary conditions in such case. A domain decomposition method called Total Finite Element Tearing and Interconnection (TFETI) method is used to perform the analysis. The proposed method of enlarging the size of the RVE using identical copies of the base cell and then using TFETI to computationally solve the problem is referred to as the Augmented TFETI method. Here subdomain level computations for the unit cell are directly used while performing calculations using the RVE. To demonstrate the applicability of the method, sample problem of finite size and having periodic microstructure is solved using the Augmented TFETI. It consists of a cell which has an eccentric hole embedded in an isotropic matrix. Uniform displacements are applied to the RVE's of increasing size. It is seen that the results obtained using RVE's of different sizes converge as the sizes of the RVEs increase. In addition the computational performance of the propose method is compared to that of using the standard finite element to solve problem with increased RVE size. It was also observed that the augmented TFETI is 50% computationally more efficient than the standard FEM applied to the RVE's with increased size.

EFFECT OF MICRON-SCALE CONSTITUTIVE AND DAMAGE MODELING ON MULTISCALE CRACK PREDICTION IN POLYMER-MATRIX COMPOSITE LAMINATES

Key words: Multiscale Modeling, Polymer-Matrix Composites, Failure Prediction

Abstract. Damage accumulation on the fiber-diameter scale causes failure of carbon fiber-reinforced plastics (CFRPs). Therefore, microscopic damage prediction is important to evaluate structural safety of composite structures made from CFRPs. In this study, effect of matrix modeling on the fiber-diameter scale is investigated using a multiscale approach that consists of macroscopic and microscopic analyses. On the macroscopic analysis, laminate-scale finite-element analysis assuming each lamina to be a homogeneous body is conducted to obtain strain histories at failure-expected points. On the microscopic analysis, periodic unit-cell (PUC) analysis considering heterogeneity of materials is performed to predict initiation of crack in the matrix phase of CFRP, based on strain histories obtained from macroscopic analysis. Two constitutive models and four sets of failure criteria are applied to the matrix phase on the PUC analysis, and compared with each other to evaluate important factors in multiscale failure prediction of CFRP laminates.

1 INTRODUCTION

Carbon fiber reinforced plastics (CFRPs) have been widely applied to aircraft structures because of their excellent mechanical properties. In the structures made of CFRPs, the initial cracking strain has been utilized as one of the design criteria of structures. However, it is difficult to accurately predict the initial cracking strain due to structural features of CFRP laminate, such as stacking sequence, free surface, ply drop-off, and heterogeneous microscopic

structure. These structural features cause inhomogeneous stress fields in laminate, and affect fiber-diameter scale crack formation. Therefore, development of accurate multiscale analysis methods that can consider both macroscopic deformation behavior and microscopic material structure is desired.

Thermosetting or thermoplastic resin used for polymer-matrix composites exhibits nonlinear inelastic behavior with damage evolution[1, 2]. To predict such nonlinear deformation and damage evolution of polymers, various constitutive and damage models have been developed[1, 3-7], and implemented into the fiber-diameter scale unit-cell analysis[4, 7-9]. These studies provide good understanding of micron-scale failure events in polymer-matrix composites. However, comprehensive evaluation of constitutive and damage models for the matrix phase of composites under practical loading conditions is still limited.

In this study, influence of constitutive models and failure criteria applied to matrix resin on crack prediction capability of multiscale analysis is investigated. Multiscale analysis, which consists of macroscopic finite-element (FE) analysis and microscopic periodic unit-cell (PUC) analysis, is developed. Two constitutive models and four sets of failure criteria are implemented to PUC analysis, and simulated results are compared with experiment in the previous studies to evaluate factors that need to consider for initial crack prediction in CFRP laminate.

2 SIMULATION METHOD

In this study, in order to evaluate important factors in failure criteria for the matrix phase of CFRP, constitutive models and failure criteria for microscopic crack prediction are examined through the comparison of simulated results with experiment data in the previous studies[10]. In this section, macroscopic FE analysis and microscopic PUC analysis are explained, and then two-scale simulation procedure is described.

2.1 Macroscopic FE analysis of unidirectional laminates

Unidirectional CFRP laminates under off-axis loading exhibit nonlinear stress-strain behavior because of plastic deformation of matrix resin. To reproduce this nonlinear behavior, macroscopic analysis is conducted based on an anisotropic elasto-plastic constitutive law proposed by Yokozeki et al.[11]. Implementation of the constitutive law in multiscale analysis is described in the literature[12]. The material properties used in the macroscopic analysis are listed in Table 1.

A schematic view of the computational model is presented in Fig. 1. The fiber angles of

unidirectional laminates are 10°, 20°, 25°, 30°, 35°, 40°, 45°, and 90°. The length of the computational model and the assumed initial cracking site are determined based on the literature[12, 13, 14]. Incremental uniaxial displacement is applied to the edge of the analysis model with the displacement rate of 0.01 mm/s.

2.2 Microscopic periodic unit-cell analysis

To predict crack initiation under several loading conditions, a three-dimensional unit-cell model, which consists of five carbon fibers and matrix resin, is utilized. A FE model used for microscopic analysis is shown in Fig. 2. The carbon fiber is modeled as an orthotropic elastic body, and the matrix resin is modeled as an isotropic inelastic body explained later. The fiber diameter is 5 μm, and the fiber volume fraction is 56%. In this study, the interface between fiber and matrix resin is assumed to be perfectly bonding to focus on only matrix cracking. In addition, the periodic boundary condition is imposed on the unit-cell model. Material properties used in the PUC analysis are listed in Table 2.

To evaluate the effect of matrix constitutive modeling on two-scale FE analysis, two constitutive models were applied to matrix resin of PUC analysis. First one is an elasto-viscoplastic model[3] proposed to reproduce mechanical responses of ductile polymers. This

Matrix's coefficient of thermal expansion α_m	60×10^{-6} /K

model includes a one-parameter damage variable based on the hypothesis of strain equivalence.

$$\dot{\boldsymbol{\sigma}} = \left(1- \quad ^{*}\right)\boldsymbol{C}_{\mathrm{m}}^{\mathrm{e}} : \dot{\boldsymbol{\varepsilon}} - \left(1- \quad ^{*}\right)\frac{3\mu\dot{\bar{\varepsilon}}^{\mathrm{p}}}{\bar{\sigma}}\boldsymbol{\sigma}' - \frac{\dot{} \ ^{*}}{1- \quad ^{*}}\boldsymbol{\sigma} \tag{1}$$

Here, $\boldsymbol{\sigma}$ is the stress tensor, $\boldsymbol{C}_{\mathrm{m}}$ is the elastic stiffness tensor for the matrix resin, $\boldsymbol{\varepsilon}$ is the strain tensor, μ is the Lamé constant, $\bar{\varepsilon}^{\mathrm{p}}$ is the equivalent plastic strain, $\bar{\sigma}$ is the von Mises stress, $\boldsymbol{\sigma}'$ is the deviatoric stress tensor, and * is the scalar variable that gives the stiffness degradation rate. The equivalent plastic strain rate $\dot{\bar{\varepsilon}}^{\mathrm{p}}$ is determined by the following equation used by Matsuda et al.[15], including hydrostatic stress dependence[9]:

$$\dot{\bar{\varepsilon}}^{\mathrm{p}} = \dot{\varepsilon}_{\mathrm{r}}\left(\frac{\bar{\sigma}+\beta\sigma_{\mathrm{m}}}{g\left(\bar{\varepsilon}^{\mathrm{p}}\right)}\right)^{\frac{1}{m}}, \tag{2}$$

$$g\left(\bar{\varepsilon}^{\mathrm{p}}\right) = g_1\left(\bar{\varepsilon}^{\mathrm{p}}\right)^{g_2} + g_3 . \tag{3}$$

Here, $\dot{\varepsilon}_{\mathrm{r}}$ is the reference strain rate; σ_{m} is hydrostatic stress; m is an exponent regarding strain-rate sensitivity; β is hydrostatic stress sensitivity; and g_1, g_2 and g_3 are material constants.

The second model is an inelastic constitutive model[1] that accounts for the effect of free volume variation in polymer on mechanical responses.

$$\dot{\boldsymbol{\sigma}} = \boldsymbol{C}_{\mathrm{m}}^{\mathrm{e}} : \dot{\boldsymbol{\varepsilon}} - \frac{\sqrt{2}\ \dot{\gamma}^{\mathrm{p}}}{\tau}\boldsymbol{\sigma}' , \tag{4}$$

where

$$\dot{\gamma}^{\mathrm{p}} = \dot{\gamma}_0 \int_0^{\infty} \psi\left(\Delta F\right)\left[\exp\left\{ -\frac{\Delta F - \tau\, \Delta v_{\tau}^{*}(\ \ )}{\ } \right\} - \exp\left\{ -\frac{\Delta F + \tau\, \Delta v_{\tau}^{*}(\ \ )}{\ } \right\} \exp\left\{ \text{—} \right\} \right] \mathrm{d}\Delta F . \tag{5}$$

Here, $\dot{\gamma}_0$ is macroscopic inelastic strain rate, ΔF is an activation energy for transformation, ψ is a probability density function of activation energy, τ is equivalent shear stress, is temperature, Δv_{τ}^{*} is shear activation volume, is the Boltzmann constant, and is local transformation strain energy. Detailed expressions of variable's evolution laws are described in the literature[1].

Material parameters used for each constitutive model were identified through the comparison of neat-resin FE analysis with neat-resin experiment of Fiedler et al.[2]. We employed $\dot{\varepsilon}_{\mathrm{r}}$ = 1.0 × 10^{-5}, m = 1/35, β = 0.2, g_1 = 90 MPa, g_2 = 0.08, and g_3 = 20 MPa for Eqs. (2) and (3); and $\dot{\gamma}_0$ = 1.51 × 10^{7} 1/s, = 297 K, and Δv_{τ}^{*} = 1.24 × 10^{-18} mm^3 for Eq. (5).

To investigate important factors in failure criteria of composites, four sets of failure criteria are applied to matrix resin individually. Three criteria predict crack initiation based on the tensile and compressive strengths of matrix. Another criterion models crack initiation under elastic and plastic deformation, using two failure models.

The first criterion is von Mises criterion, expressed by the following equation.

$$\frac{1}{2}\left[\left(\sigma_{11} - \sigma_{22}\right)^2 + \left(\sigma_{22} - \sigma_{33}\right)^2 + \left(\sigma_{33} - \sigma_{11}\right)^2 \right] + 3\left(\sigma_{12}^2 + \sigma_{23}^2 + \sigma_{31}^2\right) \leq \ ^2 \tag{6}$$

Here, σ_i is the stress component with respect to material principal axis, and is tensile strength of matrix resin.

The second criterion is Drucker-Prager criterion[16], which includes the hydrostatic stress

effect on yielding behavior.

$$\frac{3}{2}\left(\frac{1}{-}-\frac{1}{-}\right)\sigma_{\mathrm{m}}+\frac{1}{2}\left(\frac{1}{-}+\frac{1}{-}\right)\bar{\sigma}\le 1 \tag{7}$$

Here, is compressive strength of matrix resin.

The third criterion is Christensen's failure criterion[5], which considers brittle failure under elastic deformation as well as ductile failure under plastic deformation.

$$3\left(1-\frac{}{}\right)\hat{\sigma}_{\mathrm{m}}+\hat{\bar{\sigma}}^{2}\le \frac{}{} \tag{8}$$

Here, $\hat{\sigma}_{\mathrm{m}}$ and $\hat{\bar{\sigma}}$ are hydrostatic and equivalent stresses normalized by compressive strength , respectively. On the PUC analysis with Eq. (7), (8), or (9), * in Eq. (1) is set at zero to independently evaluate each failure criterion, and a matrix crack is assumed to occur when the stress state in an element satisfies each equation.

The fourth criterion is the combined criterion[12] that consists of two failure models to predict brittle failure under elastic deformation and ductile failure under plastic deformation. The first model is the dilatational energy density criterion, proposed by Asp et al.[6]. The dilatational energy density of a linear elastic body, U_{v}, is given by

$$U_{\mathrm{v}}=\frac{3(1-2\nu)}{2E}\sigma_{\mathrm{m}}^{2} \tag{9}$$

where ν is Poisson's ratio and E is Young's modulus. A matrix crack is assumed to occur when U_{v} reaches a critical value, $U_{\mathrm{v}}^{\mathrm{crit}}$, under elastic deformation. We employ $U_{\mathrm{v}}^{\mathrm{crit}}$ = 0.9 MPa, referring to the literature[12]. The second model is based on the damage parameter, , calculated by the following evolutionary equation[7], which is based on the Gurson-Tvergaard-Needleman model[17, 18].

$$\dot{} = \quad (\bar{\sigma}-\sigma_{\mathrm{Y}})(1- \quad)\quad \left\langle \dot{\varepsilon}_{\mathrm{m}}^{\mathrm{p}} \right\rangle + (\ _{0}+\ _{1}\ )\dot{\bar{\varepsilon}}^{\mathrm{p}}. \tag{10}$$

Here,

$$\left\langle \dot{\varepsilon}_{\mathrm{m}}^{\mathrm{p}} \right\rangle = \quad \left[\quad \left(\frac{\left\langle \sigma_{\mathrm{m}} \right\rangle}{\hat{\sigma}} \right)^{2} \right]^{\bullet} \tag{11}$$

The first term on the right-hand side in Eq. (10) represents void growth caused by mean plastic vertical strain, and the second term indicates damage evolution caused by shear deformation. Here, is the Heaviside function, $\hat{\sigma}$ is the reference stress, σ_{Y} is the linearity limit of the matrix resin, and , $_{0}$ and $_{1}$ are non-dimensional constants. We employ $\hat{\sigma}$ = 73

MPa, = 1.5, $_0$ = 0.6, and $_1$ = 0.6, referring to the literature[12]. * is introduced to include the effect of the rapid evolution of damage due to the coalescence of micro voids[18].

$$^* = \begin{cases} & (< _c) \\ _c + \dfrac{^{*crit} - _c}{^{crit} - _c}(- _c) & (\geq _c) \end{cases} \tag{12}$$

Rapid damage evolution starts when reaches the threshold value $_c$. Here, ^{crit} is the critical value of , and ^{*crit} is the critical value of *. A matrix crack is assumed to occur when reaches the critical value, ^{crit}, under plastic deformation. We utilize $_c$ = 0.08, ^{crit} =0.25, and ^{*crit} = 1/1.5, referring to the literature[19]. Furthermore, to avoid the mesh dependence of matrix damage, the nonlocalization of the variables that relate to failure criteria is conducted according to the literature[20].

2.3 Computational procedure

To consider microscopic structure of composites and macroscopic deformation behavior of laminate simultaneously, multiscale analysis that consists of microscopic PUC analysis and macroscopic FE analysis is carried out. The computational procedure of the multiscale analysis is summarized as follows.

1) On the macroscopic scale, displacement-controlled tensile test analysis is performed to predict strain fields in laminate. The strain history is extracted at the assumed crack initiation point presented in Fig. 1.
2) On the PUC analysis, temperature decrease analysis is carried out to calculate thermal residual stress generated in the manufacturing process. Through the analysis, temperature is decreased by 150 K, which corresponds to the difference from curing temperature to room temperature. Macroscopic strain increment, which is uniformly applied to whole unit-cell, is controlled in order that volume-averaged stress of unit-cell will be zero, which reproduces the thermal shrinkage of laminate. Stress and strain fields obtained from this calculation are defined as initial states of laminate.
3) Macroscopic strain increment based on the strain history obtained from procedure 1) is applied to unit-cell to predict crack initiation in laminate subjected to tensile loading. Initial cracking strain is defined as the applied strain of the laminate when the failure criterion described in the section **2.2** is firstly satisfied in an element.

3 RESULTS AND DISCUSSION

Firstly, the effect of matrix constitutive modeling on laminate nonlinear response prediction was examined. Figure 3 shows the comparison of simulated results obtained from PUC analysis with experiment data of Yoshioka et al.[10]. The horizontal axis indicates applied strain, and the vertical axis represents volume-averaged stress over the unit cell. Multiscale predictions with both constitutive models reproduced inelastic stress-strain relationship of laminate. In the case of unidirectional laminate under off-axis loading, appropriate constitutive modeling, which is established based on experiment data, provides reasonable prediction of nonlinear stress-strain response.

Failure criteria were compared with each other, using the constitutive model of Eq. (1). Parameters and were identified through the comparison of simulated cracking strains with experiment results of unidirectional off-axis tensile tests conducted by Yoshioka et al.[10]. Figure 4 shows simulated failure strains obtained from multiscale analysis with each failure criteria, using identified parameters. Except for von Mises criterion, simulated results qualitatively agree with experiment data. The identified parameters and shown in Fig. 4 are feasible because these values are in the range of experimentally measured strength[2, 21].

For more detailed evaluation, initial cracking sites obtained from each failure criterion were compared. Figure 5 shows the initial cracking sites predicted by each failure criterion in the 30° off-axis test. The hydrostatic and equivalent stress distributions obtained from the PUC analysis with the combined criterion are also shown in Fig. 5. In this case, initial crack was initiated

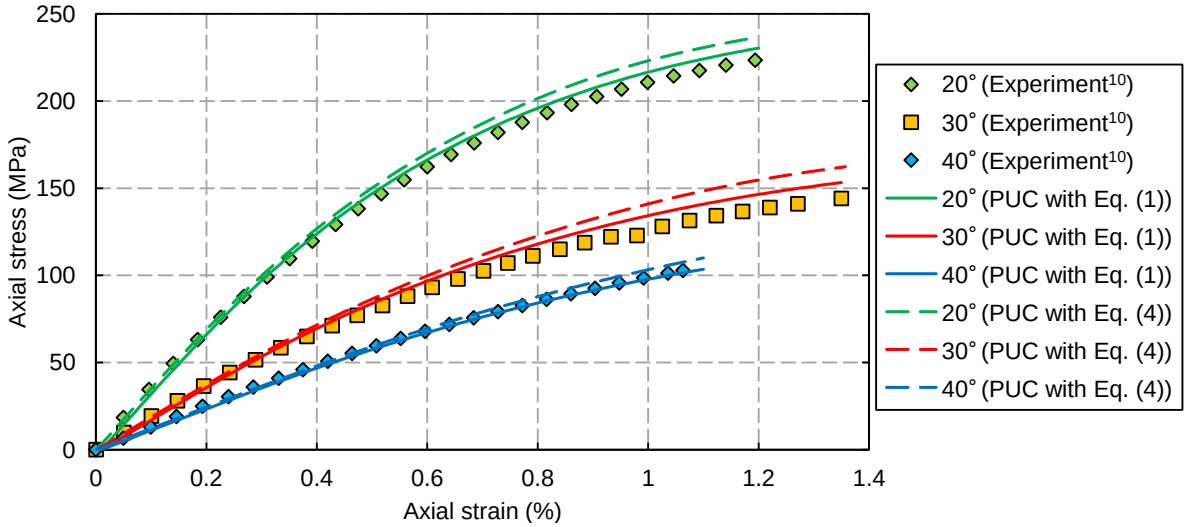

Fig. 3 Comparison of simulated off-axis tensile response of laminate with experiment data.

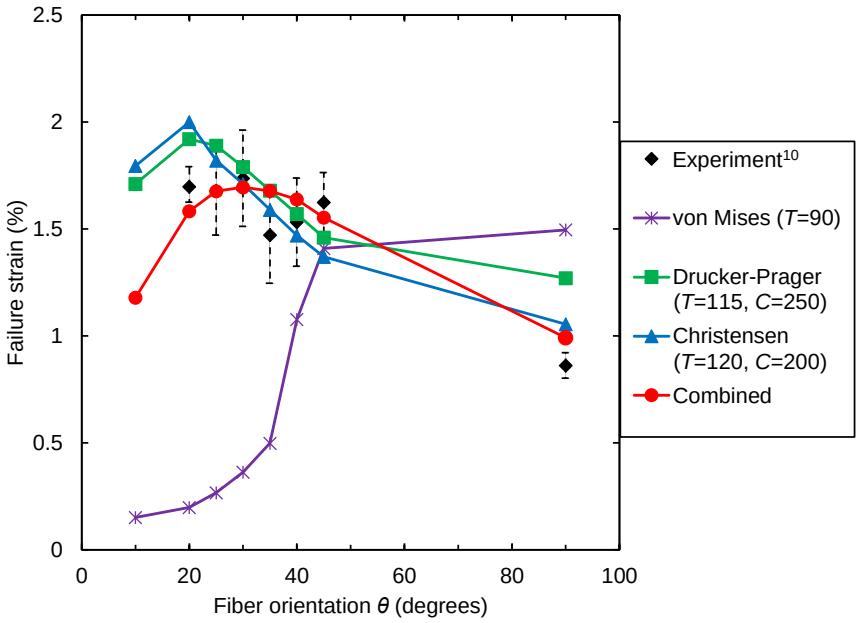

Fig. 4 Comparison of initial cracking strains obtained from multiscale analysis with experiment.

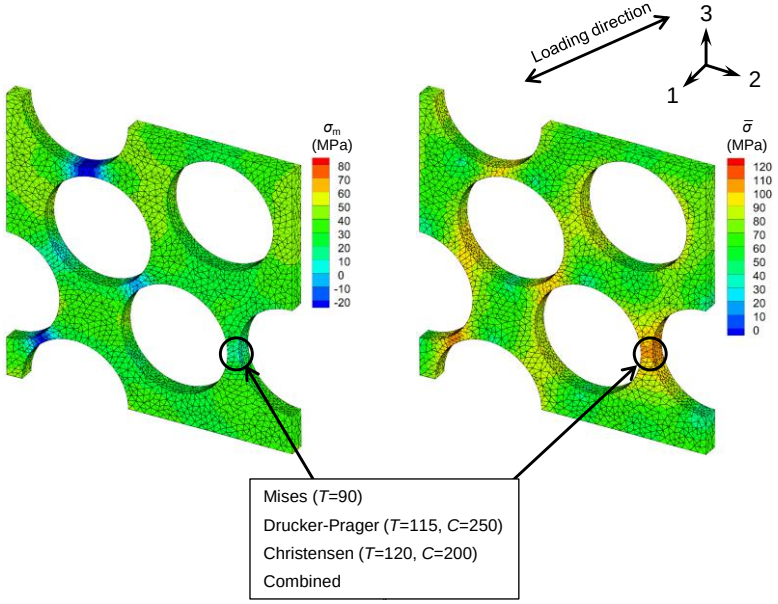

Fig. 5 Initial cracking sites predicted by each failure criterion and hydrostatic and equivalent stress distribution obtained from 30° off-axis analysis with combined criterion.

between fibers where large equivalent stress occurs. This large equivalent stress was caused by the shear deformation of laminate, and it led to crack formation under plastic deformation.

Figure 6 shows the initial cracking sites predicted by each failure criterion in the transverse

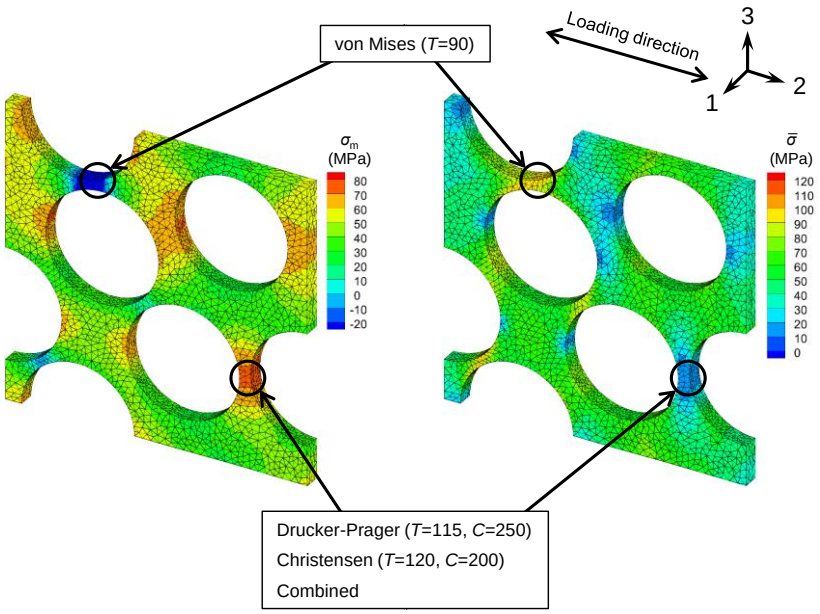

Fig. 6 Initial cracking sites predicted by each failure criterion and hydrostatic and equivalent stress distribution obtained from 90° off-axis analysis with combined criterion.

tension test. Figure 6 also shows the hydrostatic and equivalent stress distributions obtained from the PUC analysis with the combined criterion. In the case of the Drucker-Prager, Christensen and combined criteria, the initial crack occurred between fibers that are aligned parallel to the loading direction. These results agree well with previous experimental work[21] and numerical results[8, 9]. On the other hand, in the case of von Mises criterion, the initial crack was initiated between fibers that are aligned perpendicular to the loading direction. The von Mises criterion cannot reproduce the initial cracking site under transverse loading because this criterion does not consider the hydrostatic stress effect that causes cavitation-induced brittle failure reported by Asp et al.[6, 8]. These results indicate that a failure criterion for matrix resin should include not only the distortional component that causes ductile failure but also the dilatational component that induces brittle failure to predict initial failure under practical loading conditions.

4 CONCLUSIONS

In this study, the effect of constitutive and failure modeling of matrix resin on crack prediction capability of multiscale analysis is investigated. Two constitutive models were applied to matrix resin of PUC analysis to examine their influence on nonlinear stress-strain

response prediction of CFRP laminate. For unidirectional laminate, inelastic constitutive models with experimentally identified parameters provided reasonable multiscale prediction of material nonlinearity. Four sets of failure criteria were implemented to microscopic PUC analysis to evaluate factors that need to predict crack initiation in composite laminate. Except for von Mises criterion, simulated results qualitatively agreed with experiment data. This is because von Mises criterion does not consider the hydrostatic stress effect on crack formation. These results imply that a failure criterion for matrix resin ought to take account for not only the distortional effect that leads to ductile failure but also the dilatational effect that induces brittle failure to predict crack formation. We will conduct multiscale matrix modeling evaluation with practical laminate to develop matrix modeling strategy for multiscale failure prediction, which is capable under more complex loading conditions.

Hydrodynamics and Nutrient Transport Inside a Cell-Seeded Hollow Fibre Membrane Bioreactor

Prakash Kumar*, Raja Sekhar G. P.**

*Indian Institute of Technology Kharagpur, India 721302, **Indian Institute of Technology Kharagpur, India 721302

ABSTRACT

Introduction Biodegradable extracellular matrix (ECM), also termed as the scaffold, are manufactured using natural materials such as collagen, glycosaminoglycan, and chitosan. In addition to natural materials, artificially synthetic polymers like polyglycolic acid (PGA), polylactic acid (PLA), and polycaprolactone (PCL) have also been used; moreover, most of the products used are deformable in nature [1]. The objective of this study is to provide a mathematical model of HFMB bioreactor along with deformable scaffold so that a uniform distribution of nutrient concentration can be supplied to each part of the bioreactor. Methods In order to deal with deformation of the solid phase and movement of the fluid phase, we adopt biphasic mixture theory equations [2]. The flow inside the lumen is governed by Stokes equation. We close the model using the appropriate boundary conditions at the wall and the interphase of the bioreactor. The flow inside the bioreactor is assumed to be unidirectional and the advection-diffusion-reaction equation is used to get the momentum balance of the nutrient in scaffold and lumen region. We use asymptotic methods to reduce the system (lubrication approximation) to obtain leading order nutrient concentration. This leads to a coupled system of partial differential equations (PDEs) with time-dependent variables. Laplace transformation is used to deal with time-dependent terms and Durbin's algorithm was used to retrieve time dependency. Results The effect of fluid velocity and the solid displacement is analyzed with respect to varying pressure gradient, porosity, the permeability of the scaffold region. The convection in the nutrient balance equation is affected by the composite velocity inside the scaffold region. The reaction rate of different cells based on available experimental data is used to study the effect on nutrient concentration. The factors affecting the nutrient concentration are lumen radius, porosity, and permeability of the scaffold, Thiele modulus, pressure gradient etc. Total mass transfer rate is computed to analyze the movement of nutrient supply in each cross-section of the bioreactor. Nutrient concentration inside the bioreactor increases with increase in the thickness of the lumen whereas porosity and permeability have significant role in the uniformity of nutrient concentration. Nutrient concentration decreases with higher Thiele modulus and the mass transfer increases with the increase in the thickness of scaffold region. References 1. P. Chumtong, et al. A C 0 Interior Penalty Discontinous Galerkin Method for Fourth Order Total Variation Flow

Rahul Kumar*, Chandi Bhandari**, Ronald H.W Hoppe***

*Basque Center for Applied Mathematics (BCAM), Bilbao, Spain, **University of Houston, Houston, ***University of Houston, Houston, USA

ABSTRACT

We consider the numerical solution of the regularized fourth order total variation flow problem based on an implicit discretization in time and a C 0 Interior Penalty Discontinuous Galerkin (C 0 IPDG) method in space. In particular, we prove coerciveness and boundedness of the associated C 0 IPDG form with respect to a mesh dependent C 0 IPDG-norm of the underlying func- tion space. The main result is an a priori error estimate of the global discretization error in the mesh dependent C 0 IPDG-norm. The derivation of the error estimate requires an Aubin-Nitsche type argument by considering an appropriate boundary value problem for the adjoint of the linearized partial differential operator. Numerical results are also provided illus- trating the performance of the C 0 IPDG method and confirming the theoretical findings. Finally documentation of applications to medical imaging will be produced.

Enhanced Local Maximum Entropy Approximation for Stable Meshfree Simulations

Siddhant Kumar*, Dennis Kochmann**, Kostas Danas***

*California Institute of Technology, **ETH Zürich, ***École Polytechnique

ABSTRACT

We propose an improved meshfree approximation scheme which is based on the local maximum-entropy strategy as a compromise between shape function locality and entropy in an information-theoretical sense. The improved version is specifically designed for severe, finite deformation and offers significantly enhanced stability as opposed to the original formulation. This is achieved by (i) formulating the quasi-static mechanical boundary value problem in a suitable updated-Lagrangian setting, (ii) introducing anisotropy in the shape function support to accommodate directional variations in nodal spacing with increasing deformation, (iii) spatially bounded shape function support to restrict the domain of influence and increase efficiency, (iv) truncating shape functions at interfaces in order to stably represent multi-component systems like composites or polycrystals. The new scheme is applied to benchmark problems of severe elastic deformation that demonstrate its performance both in terms of accuracy (as compared to exact solutions and, where applicable, finite element simulations) and efficiency. Importantly, the presented formulation overcomes the classical tensile instability found in most meshfree interpolation schemes, as shown for stable simulations of, e.g., the inhomogeneous extension of a hyperelastic block up to 300% or the torsion of a hyperelastic cube by 270 degrees – both without the need for remeshing.

A Cluster-based Microstructural Topology Optimization

Tej Kumar*, Krishnan Suresh**

*University of Wisconsin, Madison, **University of Wisconsin, Madison

ABSTRACT

The advent of 3D printing has enabled the possibility of custom designed microstructures for demanding applications. Microstructures were initially employed in structural optimization to create repeating structures using a single set of microstructural design variables. Later, macro-structural variables were included together with a local volume constraint to achieve a two-level optimization [1, 2]. The local volume constraint was found to be essential to avoid completely degenerate (entirely solid, or entirely void) microstructures. However, this additional constraint inhibited the design from achieving peak performance. Here, we propose to get rid of both the macro-structural variables, as well as the local volume constraint. Instead, we directly impose a volume constraint via the microstructural variables. This leads to spatially varying, and optimal, microstructures. To address the computational cost, we generalize the grid-based clustering strategy proposed in Sivapuram et al. [1]. In particular, we propose several alternate clustering strategies that lead to significant improvement in performance, without significantly affecting the computational cost. Clusters are allowed to remain fixed or can adapt, during optimization. The clustering strategies are developed based on the well-known k-clustering algorithm, using multiple metrics. The effectiveness of these strategies is demonstrated through several examples. Associated computational cost and performance are studied with varying number of clusters. Numerical Modeling of Contact Friction Problems Using Phase-Field Model of Fracture

Vivek Kumar*, Maurizio Chiaramonte**

*Civil and Environmental Engineering Dept, Princeton, NJ, **Civil and Environmental Engineering Dept, Princeton, NJ

ABSTRACT

Correctly predicting the behavior of faults and fissures in rocks or concrete-to-concrete sliding in civil engineering structures is important to prevent structural failure. These essentially turn into solving contact problems between fractured surfaces. Earlier approaches to solve contact problems based on extended finite element method (X-FEM) suffer from numerical instability and the contact pressure so obtained between cracked surfaces show spurious oscillations. Moreover, these oscillations persist or become worse with mesh refinement. Hence, various stabilization techniques had to be employed to overcome the numerical instability. Some of the commonly employed stabilization techniques are Nitsche's stabilization, bubble stabilization, reduced Lagrange methods and polynomial pressure projection. In this article we discuss a new method for solving frictional contact problems which do not suffer from such issues In this work, we develop a phase-field model of fracture for solving frictional contact problems. Phase field model is a diffusive model of fracture based on the introduction of an auxiliary field called phase field. The phase-field model used in this article is based on the work of Miehe et. al [Miehe C, Hofacker M, Welschinger F. A phase field model for rate-independent crack propagation: Robust algorithmic implementation based on operator splits. Computer Methods in Applied Mechanics and Engineering. 2010 Nov 15;199(45):2765-78.]. We detail the mathematical formulation for extending the use of phase-field for frictional contact problems and implement the scheme using FEniCS, an open source computing platform for solving partial differential equations. Benchmark problems involving both frictionless and frictional contact are solved to demonstrate the advantages of this new method. Finally, the above method is used to simulate the crack growth when surfaces with frictional contact move past each other, and the results are compared with those found in literature.

On the Combination of Extended Galerkin Methods with Mesh Adaptation

Florian Kummer*

*TU Darmstadt/Fluid Dynamics

ABSTRACT

Over the past years, we developed a high-order numerical method for multi-phase flow problems, such as droplets or bubbles, which employs a sharp interface representation by a level-set and an extended discontinuous Galerkin (XDG) discretization for the flow properties. The shape of the XDG basis functions is dynamically adapted to the position of the fluid interface, so that the spatial approximation space can represent jumps in pressure and kinks in velocity accurately. By this approach, the high-order convergence property of the discontinuous Galerkin (DG) method can be preserved for the low-regularity, discontinuous solutions, such as those appearing in multi-phase flows. However, in realistic droplet setups one observes length scales which may cover several magnitudes. While extended methods are well suited to embed arbitrary interfaces or surfaces on (e.g. Cartesian) background meshes they lack the capability to adapt to different length scales. Therefore, an extended method has to be combined with techniques like adaptive mesh refinement. This refinement can be feature-based, e.g. controlled by the local curvature of the fluid interface. Our presentation will focus on some of the critical building-blocks of the method and their integration in the full solver.

The Lie Symmetries of Forced Duffing Type Oscillators

Bidisha Kundu*, Ranjan Ganguli**

*Ph.D Student, **Professor

ABSTRACT

In the era of advanced computation techniques and tools, still, the researchers are interested in inventing new ways of calculation. Their interests lie in searching analytical solutions, exact or closed form of the solutions to save the computation time. The Lie symmetry method is the most famous and successful among them for applying on different types of differential equations. The Norwegian mathematician Sophus Lie (1842-1899) first introduced this technique and later it was developed more and employed in several problems [1]. This method is the mixture of two branches of mathematics- algebra and analysis. There are various kinds of motivations for studying the Lie method such as to find the symmetries of the system, an equivalent form of the equation by reducing the order of the equation or linearize the nonlinear equation, and the invariant solutions which are in exact or closed form in most of the cases. In this work, we mainly concentrate on the nonlinear damped spring-mass system with external force. Due to nonlinear restoring force (Duffing oscillator), or for the damping (van der Pol oscillator), the nonlinearities appear. In [2], the general Liénard type equations were studied but without forcing effect. We follow the Lie symmetry procedure to understand the symmetries and try to find the similarity transformation dependent on the damping coefficient, force etc. Duffing type oscillators with external force effect are studied here. So, time variable is explicitly present in the equation, and the equation is nonautonomous. In this case, the Lie method will help us to investigate this system to get the invariant solution, and it may also linearize the equation. In this presentation, at first, I will discuss the fundamental theories and background of the Lie method and the application procedure. The primary challenge is to solve the determining equations which provide the transformations. We have solved them analytically and found a relationship between the damping coefficient, stiffness nonlinearity and the force. We hope we can extract more information and extend our work to coupled Duffing type oscillators. References: [1] Olver P. J., Applications of Lie Groups to Differential Equations, vol. 107 (Springer Science & Business Media, New York, 2012). [2] Pandey, S.N., Bindu, P.S., Senthilvelan, M., Lakshmanan, M., J. Math. ABSTRACT

Intracranial aneurysms (ICAs) are localized dilations of blood vessels in the brain caused by weaknesses in the vessel walls. ICAs have a prevalence of 0.5% - 6% in adults. While the aneurysm itself is typically asymptotic, incidental rupture of an ICA produces subarachnoid hemorrhage (SAH), leading to 5% of all strokes and the death of roughly 10% of patients before receiving medical attention [1]. Computational fluid dynamic (CFD) modeling of the hemodynamics of ICAs can be used by physicians to inform the treatment process once an aneurysm has been diagnosed. The objective of this study is to develop a CFD model for simulating the velocity patterns within ICAs, and eventually for accommodating a novel endovascular treatment method utilizing an aliphatic urethane shape memory polymer. The CFD model will be developed from patient-specific brain computed tomography (CT) angiography in ANSYS Fluent. The model will be validated using in-house particle image velocimetry (PIV) analysis of patient-specific aneurysm phantoms under pulsatile flow conditions. The current clinical practice includes two main treatment methods for ICAs— a clipping device that is surgically attached around the outer neck of the aneurysm and an endovascular embolization method that uses an intravenous delivery device to coil flexible wire within aneurysm sac [2]. We are developing a novel treatment using patient-specific shape memory polymer (SMP) inserts for an endovascular embolization technique capable of achieving a higher volume fill rate and providing more permanent occlusion. CFD is used to evaluate which treatment method will result in the most favorable flow conditions once implemented. For our innovative therapeutics, we plan to use a stereolithographic 3D printer to cure SMP in geometries based on CT scan image data from individual patients. The SMP will then be deformed into a thin filament capable of being delivered intravenously, and will be thermally activated to revert to its original geometry once arriving at the aneurysm. To properly demonstrate the feasibility of this treatment, the developed CFD model will need to accurately predict the velocity patterns within the untreated aneurysm, and account for interactions between the blood flow and the boundary of the SMP device. The developed CFD-based aneurysm treatment simulation platform will provide a useful tool for predicting the effectiveness of SMP based occlusion in patient-specific scenarios. References: [1] S. Micro-FE Modeling for Multiscale Coupled Analysis of Resistance Spot Welding

Hiroyuki Kuramae*, Tomoya Niho**, Tomoyoshi Horie***

*Osaka Institute of Technology, **Kyushu Institute of Technology, ***Kyushu Institute of Technology

ABSTRACT

Since electrical contact resistance is an important property in the numerical simulations for resistance spot welding, a multiscale coupled finite element (FE) procedure for resistance spot welding is proposed to evaluate the high accuracy of the electrical contact resistance. This analysis consists of macroscopic coupled FE analysis for the resistance spot welding and microscopic the electrical contact resistance analysis using three-dimensional (3D) thermal elasto-plasticity contact FE simulation. The multiscale analysis is based on coupled FE procedure among structural deformation, electric current and temperature distributions to evaluate a nugget growth by Joule heating in the macro-scale analysis, and to calculate the electrical contact resistance in the micro-scale analysis. Temperature-dependent material properties such as yield stress, work hardening rate and resistivity are considered in both scale analyses. A rigid plate is contacted to the micro-FE model with contact pressure and temperature that are obtained by macro-analysis, to calculate electrical contact resistance by elast-plasticity contact FE analysis including large deformation theory combined with electric FE analysis based on the phi-method. The micro-scale analysis is a very computationally expensive process because of evaluation of electrical contact resistance distribution on the macro-contact surface every time step. A micro-FE model, which corresponds to statistically similar representative volume element (SS-RVE), was constructed based on a surface roughness measurement of a steel sheet using laser microscope apparatus with 0.139 micrometers interval. In this study, an optimum size of SS-RVE in-plane was determined based on correlational analyses between frequency distribution of the microscopic surface roughness between measured 284.7×213.5 square micrometers and various sampling size. The optimum size of SS-RVE was determined as 100×100 square micrometers in-plane. Resolution of 3D FE mesh in-plane is also examined by the micro-scale electrical contact resistance analyses. In addition, to analyze realistic electrical contact resistance of steel plate contact in the micro-scale analysis, an oxide film FeO on the surface is considered. The oxide film is 3nm thickness and is introduced into the surface of the micro-FE model. The electrical contact resistance with the oxide film was higher accuracy than without one.

Comparison of Fracture Behavior in Concrete between FEM and DIC

Mao Kurumatani*, Yusuke Koakutsu**, Kazuya Hashiguchi***

*Ibaraki University, **Ibaraki University, ***Ibaraki University

ABSTRACT

We present a comparison of fracture behavior in reinforced concrete between simulation and experiment toward the V&V analysis which has recently been required in the field of computational mechanics. Particularly, the V&V for the fracture simulation in concrete seems to be difficult because many studies still have been made on the numerical methods for crack propagation for a long time. In this study, the FEM with a damage model is applied to simulate the fracture behavior with cracking in concrete. The damage model is based on fracture mechanics for concrete in consideration of cohesive zone in the fracture process, which is equivalent to a kind of energy balance approach in terms of fracture energy. The modified von-Mises criterion is introduced into the damage model to evaluate the cracking in concrete while the von-Mises plasticity is applied to model the plastic behavior of steel-reinforcements. To measure the crack propagation in concrete, we employ the digital image correlation (DIC) method which has been developed in our laboratory. A numerical simulation with the FEM and experimental measurement with the DIC are performed for 4-point bend test of RC beams with different shear reinforcements. The quantitative comparison of crack propagation between the numerical and experimental results offer valuable insight into the V&V for the fracture simulation of concrete and reinforced concrete.

ABSTRACT

The last few decades have seen significant advancements in materials research tools, allowing researchers to rapidly synthesis and characterize large numbers of samples - a major step toward high-throughput materials discovery. Machine learning has been tasked to aid in converting the collected materials property data into actionable knowledge, and more recently it has been used to assist in experiment design. In this talk we demonstrate the next step in machine learning for materials research - an autonomous materials measurement system. The software system controls X-ray diffraction measurement systems both in the lab and at the beamline to identify composition-temperature phase maps from composition spreads with a minimum number of measurements. The algorithm also capitalizes on prior knowledge in the form of physics theory and external databases, both theory-based and experiment-based, to more rapidly hone in on the optimal results. Materials of interest include Fe-Ga-Pd, TiO2-SnO2-ZnO, and Mn-Ni-Ge.

Abstract. New smart materials have been developed in material science, that are suitable for broad mechatronic applications. Modern mechatronic systems are focusing on minimizing size, active control and low energy consumption. To improve performance of such systems, new materials and technologies are developed – one of them, which found broad application usage in mechatronics is Functionally graded material (FGM). Connection of FGM beam with piezoelectric layers can be considered as suitable smart material composition for mechatronics. In the contribution, finite element beam with thick FGM core and thin piezoelectric layers is presented. FGM finite element beam with piezolayers has 6 structural degree of freedom and 4 electric degree of freedom. Stiffness matrix and mass matrix of beam element is computed using transfer functions and transfer constants, where the homogenization process of FGM core and piezoelectric layers is applied.

1 INTRODUCTION

Smart structures are widely used in modern engineering applications. They can combine the progress in material science, control theory, electronics and informatics. The best way how to examine such structures before their production is to create their mathematical model. Finite element method is dominant mathematical tool to analyzed such structures and with combination with control can be able to create model of smart structure.
In the presented paper, beam element with core made of functionally graded material in

transversal and longitudinal direction and with piezoelectric layers is presented. The goal is to create dynamic representation of beam structures with active parts made from piezoelectric layers, which can be also used for model of control of the structure.

2 HOMOGENIZED MATERIAL PROPERTIES OF BEAM

Let as consider straight sandwich beam with core made from functionally graded material (FGM) and top and bottom layers made from piezoelectric material with constant material properties – Fig. 1. Cross-section of FGM core has height h_{FGM} and depth b, one piezoelectric layer has height h_p and depth b.

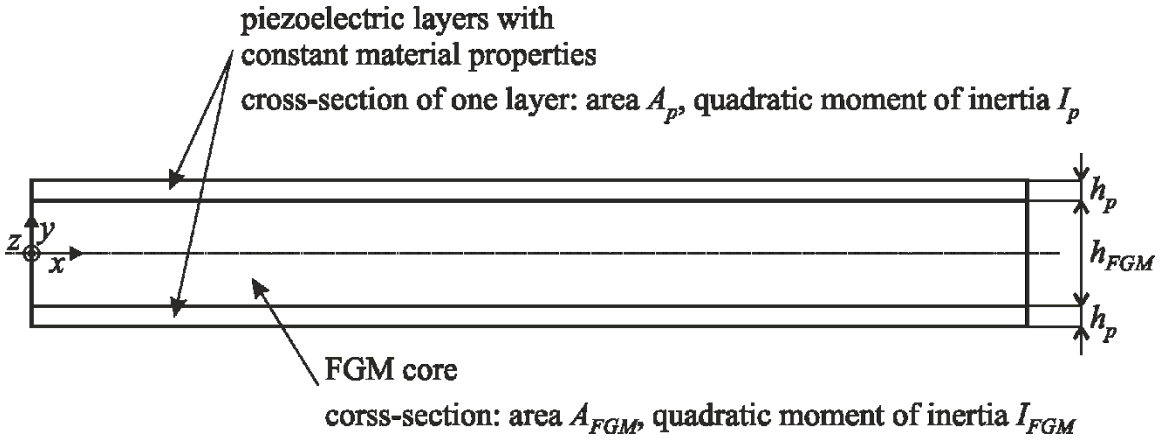

Fig. 1: Piezoelectric beam with core made from FGM material

The composite material of the FGM core arises by mixing two components (matrix and fibers) that are approximately of the same geometrical form and dimensions.
Both the fiber volume fraction $v_f(x,y)$ and matrix volume fraction $v_m(x,y)$ are chosen as a polynomial function of longitudinal position x, and with continuous and symmetrical variation through its height h with respect to the neutral plane of the FGM core. The volume fractions are assumed to be constant through the cross-section depth b. At each point of the FGM core it holds: $v_f(x,y) + v_m(x,y) = 1$.
Young modulus of the constituents (fibers - $E_f(x,y)$ and matrix - $E_m(x,y)$) can analogically vary as it is stated by the variation of volume fractions. For effective Young's modulus $E_{FGM}(x,y)$ of FGM core we can write [1,2]

$$E_{FGM}(x,y) = v_f(x,y)E_f(x,y) + v_m(x,y)E_m(x,y) \tag{1}$$

2.1 Homogenized properties of FGM core

Homogenized Young's modulus for axial loading $E_{FGM}^{HN}(x)$ and bending $E_{FGM}^{HM}(x)$ of FGM core with cross-section A_{FGM} (height h_{FGM} and depth b) and quadratic moment of inertia I_{FGM} can be expressed in form

$$E_{FGM}^{HN}(x) = \frac{\int_{-h_{FGM}/2}^{h_{FGM}/2} bE_{FGM}(x,y)dy}{A_{FGM}} \tag{2}$$

$$E_{FGM}^{HM}(x) = \frac{\int_{-h_{FGM}/2}^{h_{FGM}/2} by^2E_{FGM}(x,y)dy}{I_{FGM}} \tag{3}$$

Both homogenized Youngs' moduli of FGM core are dependent only on axial location x and not on transversal location y.

2.2 Homogenized properties of beam with FGM core and piezoelectric layers

Homogenized Young's modulus for axial loading $E^{HN}(x)$ and bending $E^{HN}(x)$ of beam with FGM core and piezoelectric layers can be expressed in form

$$E^{HN}(x) = \frac{A_{FGM}}{A}E_{FGM}^{HN}(x) + \frac{2A_p}{A}E_p \tag{4}$$

$$E^{HM}(x) = \frac{I_{FGM}}{I}E_{FGM}^{HN}(x) + \frac{2I_{pz}}{I}E_p \tag{5}$$

where A is total cross section ($A = A_{FGM} + 2A_p$), I is total quadratic moment of inertia and I_{pz} is quadratic moment of inertia of piezolayer to global axis z.
Both homogenized Youngs' moduli of beam with FGM core and piezoelectric layers are dependent only on axial location x.

3 PIEZOELECTRIC BEAM FINITE ELEMENT EQUATIONS

3.1 Piezoelectric constitutive equations

Piezoelectric constitutive equations describe the relation between mechanical and electrical quantities. The form of the constitutive equations depends on chosen mechanical and electrical quantities and can be expressed in two basic configurations. The first configuration is expressed by stress tensor components σ_{kl} and vector components of electric intensity E_k and has form

$$\begin{aligned} \varepsilon_{ij} &= d_{ijk}E_k + s_{ijkl}^E\sigma_{kl} \\ D_i &= \epsilon_{ik}^\sigma E_k + d_{ikl}\sigma_{kl} \end{aligned} \tag{6}$$

where ε_{ij} are strain tensor components, D_i are components of electric displacement vector, d_{ijk} are tensor components of piezoelectric constants, ϵ_{ik}^{σ} are components of permittivity tensor on conditions constant mechanical stress and s_{ijkl}^{E} are components of compliance tensor on conditions constant electric intensity [3].
The constitutive equations can be also expressed by strain tensor components ε_{kl} and vector components of electric intensity E_k and has form

$$\begin{aligned} \sigma_{ij} &= c_{ijkl}^{E}\varepsilon_{kl} - e_{ijk}E_k \\ D_i &= e_{ikl}\varepsilon_{kl} + \epsilon_{ik}^{\varepsilon}E_k \end{aligned} \tag{7}$$

where new quantities are components of stiffness tensor c_{ijkl}^{E} and components of piezoelectric modulus tensor e_{ikl}.
The other equations, which play important role, are relation between the components of strain tensor ε_{ij} and components of deformation u_i and relation between vector components of electric intensity E_i and electric potential φ. These relations can be expressed as

$$\begin{aligned} \varepsilon_{ij} &= 1/2\left(u_{i,j} + u_{j,i}\right) \\ E_i &= -\varphi_{,i} \end{aligned} \tag{8}$$

Tensor equations (6) and (7) can be expressed in matrix forms, which is more suitable for finite element formulations, using symmetry of mechanical and electrical quantities as well as material properties. Matrix formulations of constitutive equations (7) can be expressed as

$$\begin{aligned} \boldsymbol{\sigma} &= \boldsymbol{c}^{E}\boldsymbol{\varepsilon} - \boldsymbol{e}^{T}\boldsymbol{E} \\ \boldsymbol{D} &= \boldsymbol{e}\boldsymbol{\varepsilon} + \boldsymbol{\epsilon}^{\varepsilon}\boldsymbol{E} \end{aligned} \tag{9}$$

where $\boldsymbol{\sigma}$ is vector (in mathematical meaning) of 6 stress tensor components, $\boldsymbol{D}$ is vector of 3 electric displacement vector components, $\boldsymbol{\varepsilon}$ is vector of 6 strain tensor components, $\boldsymbol{E}$ is vector of 3 electric intensity vector components, $\boldsymbol{c}^{E}$ is 6x6 matrix of mechanical properties, $\boldsymbol{\epsilon}^{\varepsilon}$ is 3x3 matrix of electrical properties and $\boldsymbol{e}$ is 3x6 matrix of piezoelectric properties.

3.2 Piezoelectric FEM equations

Piezoelectric governing equations for dynamic problems can by obtain by Hamilton's principle, which can be written in form

$$\int_{t_1}^{t_2}(\delta L + \delta W)dt = 0 \tag{10}$$

where L is Lagrangian, W is work of external mechanical and electrical forces and t_1 and t_2 defined considered time interval. Lagrangian of piezoelectric structure is given by

$$L = T - U + W_e \tag{11}$$

where T, U and W_e is kinetic energy, potential energy and electric energy of investigated structure, respectively. They can be expressed as

$$\begin{aligned} T &= \int_{(V)} \frac{1}{2} \rho\, \dot{\boldsymbol{u}}^T\, \dot{\boldsymbol{u}}\, dV \\ U &= \int_{(V)} \frac{1}{2} \boldsymbol{\varepsilon}^T \boldsymbol{\sigma}\, dV \\ W_e &= \int_{(V)} \frac{1}{2} \boldsymbol{E}^T \boldsymbol{D}\, dV \end{aligned} \tag{12}$$

where $\dot{\boldsymbol{u}}$ is velocity vector with 3 components. Virtual work of external mechanical and electrical forces can be expressed as

$$\delta W = \sum \delta \boldsymbol{u}^T\, \boldsymbol{F} - \sum \delta\phi\; Q \tag{13}$$

where $\boldsymbol{u}$ is displacement vector with 3 components, $\boldsymbol{F}$ is force vector with 3 components, ϕ is electric scalar potential and Q is electric charge.
Hamilton's principle (10) can be using equations (12), (13) and constitutive equation (9) expressed in following form

$$\begin{aligned} \int_{t_1}^{t_2} \Big[&- \int_{(V)} \rho\; \delta \boldsymbol{u}^T\, \ddot{\boldsymbol{u}}\, dV - \int_{(V)} \delta \boldsymbol{\varepsilon}^T\, \boldsymbol{c}^E \boldsymbol{\varepsilon}\, dV + \int_{(V)} \delta \boldsymbol{\varepsilon}^T\, \boldsymbol{e}^T \boldsymbol{E}\, dV + \int_{(V)} \delta \boldsymbol{E}^T\, \boldsymbol{e}\, \boldsymbol{\varepsilon}\, dV + \\ &\int_{(V)} \delta \boldsymbol{E}^T\, \boldsymbol{\epsilon}^{\varepsilon} \boldsymbol{E}\, dV + \sum \delta \boldsymbol{u}^T\, \boldsymbol{F} - \sum \delta\phi\; Q \Big]\, dt = 0 \end{aligned} \tag{14}$$

Relationship between displacement of point and nodal displacement of finite element and between scalar electric potential of point and nodal scalar electric potential of finite element can be expressed by shape functions of element

$$\begin{aligned} \boldsymbol{u} &= \boldsymbol{N}_u \boldsymbol{u}^e \\ \phi &= \boldsymbol{N}_\phi \boldsymbol{\phi}^e \end{aligned} \tag{15}$$

$\boldsymbol{N}_u$ and $\boldsymbol{N}_\phi$ are matrices with shape functions. Relationship between components of strain and components of nodal displacements and relationship between components of electric intensity and nodal electric scalar potential have forms

$$\boldsymbol{\varepsilon} = \boldsymbol{B}_u \boldsymbol{u}^e$$
$$\boldsymbol{E} = -\boldsymbol{B}_\phi \boldsymbol{\phi}^e \tag{16}$$

$\boldsymbol{B}_u$ and $\boldsymbol{B}_\phi$ are matrices with derivative of shape functions. Hamilton's principle (10) can be rewritten by equations (15) and (16) into form

$$\int_{t_1}^{t_2} \delta(\boldsymbol{u}^e)^T \left[-\left(\int_{(V)} \boldsymbol{N}_u^T \rho\, \boldsymbol{N}_u \, dV \right) \ddot{\boldsymbol{u}}^e - \left(\int_{(V)} \boldsymbol{B}_u^T \boldsymbol{c}^E \boldsymbol{B}_u \, dV \right) \boldsymbol{u}^e - \left(\int_{(V)} \boldsymbol{B}_u^T \boldsymbol{e}^T \boldsymbol{B}_\phi \, dV \right) \boldsymbol{\phi}^e + \right.$$
$$\left. + \sum \boldsymbol{N}_u^T \boldsymbol{F} \right] dt + \int_{t_1}^{t_2} \delta(\boldsymbol{\phi}^e)^T \left[-\left(\int_{(V)} \boldsymbol{B}_\phi^T \boldsymbol{e}\, \boldsymbol{B}_u \, dV \right) \boldsymbol{u}^e + \left(\int_{(V)} \boldsymbol{B}_\phi^T \boldsymbol{\epsilon}^\varepsilon \boldsymbol{B}_\phi \, dV \right) \boldsymbol{\phi}^e - \right.$$
$$\left. \sum \boldsymbol{N}_\phi^T \, Q \right] dt = 0 \tag{17}$$

FEM equations of individual element can be derived from (17) in form

$$\begin{bmatrix} \boldsymbol{M}_{uu}^e & \boldsymbol{0}^e \\ \boldsymbol{0}^e & \boldsymbol{0}^e \end{bmatrix} \begin{bmatrix} \ddot{\boldsymbol{u}}^e \\ \ddot{\boldsymbol{\phi}}^e \end{bmatrix} + \begin{bmatrix} \boldsymbol{K}_{uu}^e & \boldsymbol{K}_{u\phi}^e \\ \boldsymbol{K}_{\phi u}^e & \boldsymbol{K}_{\phi\phi}^e \end{bmatrix} \begin{bmatrix} \boldsymbol{u}^e \\ \boldsymbol{\phi}^e \end{bmatrix} = \begin{bmatrix} \boldsymbol{F}^e \\ \boldsymbol{Q}^e \end{bmatrix} \tag{18}$$

The equation (18) represents dynamic behavior of piezoelectric material without mechanical damping. If the damping is considered, then the equation (18) has form

$$\begin{bmatrix} \boldsymbol{M}_{uu}^e & \boldsymbol{0}^e \\ \boldsymbol{0}^e & \boldsymbol{0}^e \end{bmatrix} \begin{bmatrix} \ddot{\boldsymbol{u}}^e \\ \ddot{\boldsymbol{\phi}}^e \end{bmatrix} + \begin{bmatrix} \boldsymbol{C}_{uu}^e & \boldsymbol{0}^e \\ \boldsymbol{0}^e & \boldsymbol{0}^e \end{bmatrix} \begin{bmatrix} \dot{\boldsymbol{u}}^e \\ \dot{\boldsymbol{\phi}}^e \end{bmatrix} + \begin{bmatrix} \boldsymbol{K}_{uu}^e & \boldsymbol{K}_{u\phi}^e \\ \boldsymbol{K}_{\phi u}^e & \boldsymbol{K}_{\phi\phi}^e \end{bmatrix} \begin{bmatrix} \boldsymbol{u}^e \\ \boldsymbol{\phi}^e \end{bmatrix} = \begin{bmatrix} \boldsymbol{F}^e \\ \boldsymbol{Q}^e \end{bmatrix} \tag{19}$$

where individual submatrices are defined as follows:

$\boldsymbol{M}_{uu}^e = \int_{(V)} \boldsymbol{N}_u^T \rho\, \boldsymbol{N}_u \, dV$; $\boldsymbol{K}_{uu}^e = \int_{(V)} \boldsymbol{B}_u^T \boldsymbol{c}^E \boldsymbol{B}_u \, dV$; $\boldsymbol{K}_{u\phi}^e = \int_{(V)} \boldsymbol{B}_u^T \boldsymbol{e}^T \boldsymbol{B}_\phi \, dV$;

$\boldsymbol{K}_{\phi u}^e = \int_{(V)} \boldsymbol{B}_\phi^T \boldsymbol{e}\, \boldsymbol{B}_u \, dV$; $\boldsymbol{K}_{\phi\phi}^e = \int_{(V)} \boldsymbol{B}_\phi^T \boldsymbol{\epsilon}^\varepsilon \boldsymbol{B}_\phi \, dV$; $\boldsymbol{C}_{uu}^e = \alpha \boldsymbol{M}_{uu}^e + \beta \boldsymbol{K}_{uu}^e$

$\boldsymbol{F}^e$ and $\boldsymbol{Q}^e$ represent nodal forces and nodal charges on considered element.

For whole structure we can formally write

$$\begin{bmatrix} \boldsymbol{M}_{uu} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} \end{bmatrix} \begin{bmatrix} \ddot{\boldsymbol{u}} \\ \ddot{\boldsymbol{\phi}} \end{bmatrix} + \begin{bmatrix} \boldsymbol{C}_{uu} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} \end{bmatrix} \begin{bmatrix} \dot{\boldsymbol{u}} \\ \dot{\boldsymbol{\phi}} \end{bmatrix} + \begin{bmatrix} \boldsymbol{K}_{uu} & \boldsymbol{K}_{u\phi} \\ \boldsymbol{K}_{\phi u} & \boldsymbol{K}_{\phi\phi} \end{bmatrix} \begin{bmatrix} \boldsymbol{u} \\ \boldsymbol{\phi} \end{bmatrix} = \begin{bmatrix} \boldsymbol{F} \\ \boldsymbol{Q} \end{bmatrix} \tag{20}$$

3.3 FEM equations of FGM beam with piezoelectric layers

2D beam element with piezoelectric layers and FGM core with degree of freedom is shown in Fig. 2.

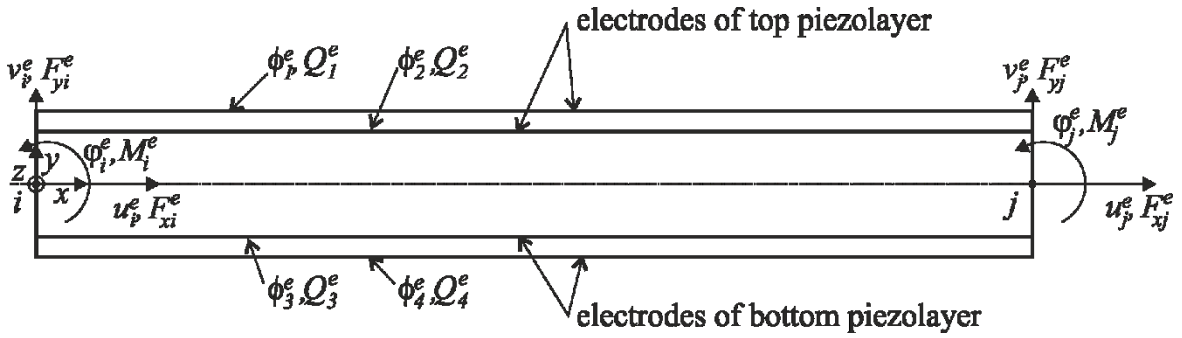

Fig. 2: 2D beam element with piezoelectric layers – degree of freedom and internal forces

Length of beam element is L^e, cross-section of FGM core is A_{FGM} and cross-section of piezolayer is A_p. Homogenized Youngs' moduli for axial loading and bending are computed according equations (4) and (5). Mechanical degree of freedom of element are displacements and rotations in both nodes $(u_i^e, v_i^e, \varphi_i^e, u_j^e, v_j^e, \varphi_j^e)$, electrical degree of freedom are electric potential on all 4 electrodes of both piezoelectric layers $(\phi_1^e, \phi_2^e, \phi_3^e, \phi_4^e)$. Internal element mechanical loads are forces and moments in both nodes $(F_{xi}^e, F_{yi}^e, M_i^e, F_{xj}^e, F_{yj}^e, M_j^e)$, internal element electric loads are electric charge on all 4 electrodes of both piezoelectric layers $(Q_1^e, Q_2^e, Q_3^e, Q_4^e)$ [4].
FEM equation of 2D piezoelectric beam with FGM core has formally the same equation as equation (20), but individual stiffness submatrices have different form, because they are using transfer constant and not classical shape functions. Mass submatrix $\boldsymbol{M}_{uu}^e$ can be constructed by classical shape functions.

The structural submatrix for the beam element with piezoelectric layers can be expressed in a form

$$\boldsymbol{K}_{uu}^e = \begin{bmatrix} k'_u & 0 & 0 & -k'_u & 0 & 0 \\ 0 & k'_{v2} & k'_{v3} & 0 & -k'_{v2} & k_{v2} \\ 0 & k'_{v3} & k'_{v33} & 0 & -k'_{v3} & k_{v3} \\ -k'_u & 0 & 0 & k'_u & 0 & 0 \\ 0 & -k'_{v2} & -k'_{v3} & 0 & k'_{v2} & -k_{v2} \\ 0 & k_{v2} & k_{v3} & 0 & -k_{v2} & k_{v23} \end{bmatrix} \tag{21}$$

Computation of individual components of the structural submatrix contains the influence of FGM core and piezoelectric layers, where homogenized material properties of beam is considered. The computation is performed numerically using concept of transfer constants.

The electrical submatrix for the beam element with piezoelectric layers can be expressed in a form

$$\boldsymbol{K}^{e}_{\phi\phi} = \begin{bmatrix} -\frac{A_p L \epsilon^{\varepsilon}}{h_p^2} & \frac{A_p L \epsilon^{\varepsilon}}{h_p^2} & 0 & 0 \\ \frac{A_p L \epsilon^{\varepsilon}}{h_p^2} & -\frac{A_p L \epsilon^{\varepsilon}}{h_p^2} & 0 & 0 \\ 0 & 0 & -\frac{A_p L \epsilon^{\varepsilon}}{h_p^2} & \frac{A_p L \epsilon^{\varepsilon}}{h_p^2} \\ 0 & 0 & \frac{A_p L \epsilon^{\varepsilon}}{h_p^2} & -\frac{A_p L \epsilon^{\varepsilon}}{h_p^2} \end{bmatrix} \tag{22}$$

where ϵ^{ε} is permitivity of piezoelectric layer under constant strain.

Submatrices of piezoelectric coupling can be expressed in following forms

$$\boldsymbol{K}^{e}_{u\phi} = \begin{bmatrix} -\frac{A_p d_{21} E_p}{h_p} & \frac{A_p d_{21} E_p}{h_p} & -\frac{A_p d_{21} E_p}{h_p} & \frac{A_p d_{21} E_p}{h_p} \\ 0 & 0 & 0 & 0 \\ \frac{A_y d_{21} E_p}{h_p} & -\frac{A_y d_{21} E_p}{h_p} & \frac{A_y d_{21} E_p}{h_p} & -\frac{A_y d_{21} E_p}{h_p} \\ \frac{A_p d_{21} E_p}{h_p} & -\frac{A_p d_{21} E_p}{h_p} & \frac{A_p d_{21} E_p}{h_p} & -\frac{A_p d_{21} E_p}{h_p} \\ 0 & 0 & 0 & 0 \\ -\frac{A_y d_{21} E_p}{h_p} & \frac{A_y d_{21} E_p}{h_p} & -\frac{A_y d_{21} E_p}{h_p} & \frac{A_y d_{21} E_p}{h_p} \end{bmatrix} \tag{23}$$

$$\boldsymbol{K}^{e}_{\phi u} = \begin{bmatrix} -\frac{A_p e_{21}}{h_p} & 0 & \frac{A_y e_{21}}{h_p} & \frac{A_p e_{21}}{h_p} & 0 & -\frac{A_y e_{21}}{h_p} \\ \frac{A_p e_{21}}{h_p} & 0 & -\frac{A_y e_{21}}{h_p} & -\frac{A_p e_{21}}{h_p} & 0 & \frac{A_y e_{21}}{h_p} \\ -\frac{A_p e_{21}}{h_p} & 0 & \frac{A_y e_{21}}{h_p} & \frac{A_p e_{21}}{h_p} & 0 & -\frac{A_y e_{21}}{h_p} \\ \frac{A_p e_{21}}{h_p} & 0 & -\frac{A_y e_{21}}{h_p} & -\frac{A_p e_{21}}{h_p} & 0 & \frac{A_y e_{21}}{h_p} \end{bmatrix} \tag{24}$$

where $A_y = \frac{1}{2} A_p \left(h_{FGM} + h_p \right)$, d_{21} and e_{21} are piezoelectric constants.

4 STATE SPACE EQUATIONS OF PIEZOELECTRIC BEAM FINITE ELEMENT

Smart structures made from piezoelectric material, are usually connected to controller in order to have required behavior of structure. For this purpose, FEM equations are transformed to state space equations [5].

The voltage actuation and charge sensing are considered. Actuation is done by imposing a voltage on the actuators and sensing by imposing a zero voltage and measuring the electric

charges appearing on the sensors. Vector of nodal displacement of the structure $\boldsymbol{u}$ can be expressed by truncated modal decomposition

$$\boldsymbol{u} = \boldsymbol{Z}\boldsymbol{x} \tag{25}$$

where $\boldsymbol{Z}$ represents chosen n modal shapes of structure and $\boldsymbol{x}$ represents modal amplitudes. Using equation (25) can be FEM equation of whole structure (20) rewritten to form

$$\boldsymbol{M}_{uu}\,\boldsymbol{Z}\ddot{\boldsymbol{x}} + \boldsymbol{C}_{uu}\boldsymbol{Z}\dot{\boldsymbol{x}} + \boldsymbol{K}_{uu}\boldsymbol{Z}\boldsymbol{x} + \boldsymbol{K}_{u\phi}\,\boldsymbol{\phi} = \boldsymbol{0} \tag{26}$$

$$\boldsymbol{K}_{\phi u}\,\boldsymbol{Z}\boldsymbol{x} + \boldsymbol{K}_{\phi\phi}\,\boldsymbol{\phi} = \boldsymbol{Q} \tag{27}$$

Using orthogonality property of mode shapes

$$\boldsymbol{Z}^T\boldsymbol{M}_{uu}\,\boldsymbol{Z} = \mathrm{diag}(\mu_k) \tag{28}$$

$$\boldsymbol{Z}^T\boldsymbol{K}_{uu}\,\boldsymbol{Z} = \mathrm{diag}(\mu_k\omega_k^2) \tag{29}$$

$$\boldsymbol{Z}^T\boldsymbol{C}_{uu}\,\boldsymbol{Z} = \mathrm{diag}(2\xi_k\mu_k\omega_k) \tag{30}$$

equations (26) and (27) can be rewritten into form

$$\boldsymbol{\mu}\,\ddot{\boldsymbol{x}} + 2\,\boldsymbol{\xi}\,\boldsymbol{\mu}\,\boldsymbol{\omega}\,\dot{\boldsymbol{x}} + \boldsymbol{\mu}\,\boldsymbol{\omega}^{\boldsymbol{2}}\,\boldsymbol{x} + \boldsymbol{Z}^T\boldsymbol{K}_{u\phi}\,\boldsymbol{\phi} = \boldsymbol{0} \tag{31}$$

$$\boldsymbol{K}_{\phi u}\,\boldsymbol{Z}\boldsymbol{x} + \boldsymbol{K}_{\phi\phi}\,\boldsymbol{\phi} = \boldsymbol{Q} \tag{32}$$

where matrices $\boldsymbol{\mu}$, $\boldsymbol{\omega}$ and $\boldsymbol{\xi}$ represent matrix of modal masses, modal frequencies and modal damping ratios of structure, respectively. After some manipulation, we can from equation (31) obtain

$$\ddot{\boldsymbol{x}} = -2\,\boldsymbol{\xi}\,\boldsymbol{\omega}\,\dot{\boldsymbol{x}} - \boldsymbol{\omega}^{\boldsymbol{2}}\,\boldsymbol{x} - \boldsymbol{\mu}^{-1}\,\boldsymbol{Z}^T\boldsymbol{K}_{u\phi}\,\boldsymbol{\phi} \tag{33}$$

Equation (33) and (32) can be rewritten into form

$$\begin{bmatrix}\dot{\boldsymbol{x}}\\ \ddot{\boldsymbol{x}}\end{bmatrix} = \begin{bmatrix}\boldsymbol{0} & \boldsymbol{I}\\ -\boldsymbol{\omega}^{\boldsymbol{2}} & -2\,\boldsymbol{\xi}\,\boldsymbol{\omega}\end{bmatrix}\begin{bmatrix}\boldsymbol{x}\\ \dot{\boldsymbol{x}}\end{bmatrix} + \begin{bmatrix}\boldsymbol{0}\\ -\boldsymbol{\mu}^{-1}\,\boldsymbol{Z}^T\boldsymbol{K}_{u\phi}\end{bmatrix}\boldsymbol{\phi} \tag{34}$$

$$\boldsymbol{Q} = [\boldsymbol{K}_{\phi u}\,\boldsymbol{Z} \quad \boldsymbol{0}]\begin{bmatrix}\boldsymbol{x}\\ \dot{\boldsymbol{x}}\end{bmatrix} + \boldsymbol{K}_{\phi\phi}\,\boldsymbol{\phi} \tag{35}$$

Equations (34) and (35) represents state space model of structure with piezoelectric sensors and actuators and can be used to analyzed structure from control viewpoint.

5 CONCLUSION

The paper presents beam finite element with piezoelectric layers, where core of the beam can be made of FGM materials. Such combination of materials is very attractive for mechatronic applications, because material composition of FGM core can be optimized for design stress state and deformation can be controlled by voltages on electrodes. FEM equations are rewritten to state space equations using truncated modal decomposition. Such model of beam structure can be easily incorporated into control model.

ABSTRACT

We report on techniques developed for and implemented in our research CFD code VirtualFluids which has been developed as a C++-library for massively parallel CFD simulation. Its modular structure includes the following functionality: hybrid block based tree type grid, generation based on geometric objects and/or CAD data, restart options for different parallel setups, D3Q27 Cumulant LBM kernel including a so-called Esoteric Twist approach to reduce memory requirements, second order accurate grid refinement, implicit turbulence model, a hybrid parallelization based on MPI and pthreads, restart/checkpointing based on MPI/IO as well as parallel In-situ visualization and output in Paraview parallel format. The code is developed using of object-oriented techniques and design patterns which foster support and functional extension. We will report on various massively parallel CFD benchmarks for real-world problems including examples running on GPGPUs and discuss future options for code extensions for usage of hybrid CPU/GPU clusters.

Limiting Techniques and hp Adaptivity for Continuous High-order Bernstein Finite Element Approximations

Dmitri Kuzmin*, Christopher Kees**, Manuel Quezada de Luna***

*TU Dortmund University, **US Army Engineer Research & Development Center, ***US Army Engineer Research & Development Center

ABSTRACT

In this talk, we present three new approaches to blending a continuous high-order Bernstein finite element discretization with a monotone piecewise-linear approximation based on the same nodal points. The first approach is a predictor-corrector method which constrains the difference between the high and low-order solutions using a localized flux-corrected transport (FCT) algorithm. The second approach constrains the difference between the residuals of the underlying discretizations using nodal limiters to adjust monotonicity-preserving artificial diffusion coefficients. This correction leads to nonlinear algebraic systems which are solved iteratively. The third approach combines the high and low-order finite element bases using a continuous piecewise-linear limiter function. This low-level limiting strategy represents a new kind of hp adaptivity. The proposed method adjusts the local order of approximation in a continuous manner while keeping the number of degrees of freedom fixed. The pros and cons of each limiting technique for high-order finite elements will be discussed and results of numerical studies for 2D test problems will be presented.

Reduced Order Models for Divergence-Conforming Isogeometric Flow Simulations

Trond Kvamsdal*, Eivind Fonn**, Harald van Brummelen***, Adil Rasheed****

*Norwegian University of Science and Technology, **SINTEF Digital, ***Eindhoven University of Technology, ****SINTEF Digital

ABSTRACT

Repetitive solutions of parametrized flow problems can be quite demanding, each solution involving a million or more degrees of freedom, that takes hours or days of computational time. A promising methodology to reduce the (on-line) computational effort is the use of Reduced Order Modelling (ROM). ROM offers the possibility to balance loss of accuracy with gain in efficiency. We have tied ROM with a divergence-conforming isogeometric high-fidelity method for incompressible flow simulations and achieved (significant) additional speedup compared to non-conforming methods. The additional speedup is related to less computations related to the so-called supremizers needed for avoiding that the ROM model get a rank-deficient velocity-pressure block. We will illustrate the performance of the development method by doing high fidelity simulations of stationary Navier-Stokes were performed of flow around a NACA0015 airfoil where we varies the inflow velocity and the angle of attack.

Performance Characteristics of a High-order Finite Element Application on a Modern High Performance Computing System – Blue Waters

JaeHyuk Kwack*, Gregory Bauer**

*National Center for Supercomputing Applications / University of Illinois at Urbana-Champaign, **National Center for Supercomputing Applications / University of Illinois at Urbana-Champaign

ABSTRACT

Performance indices of high performance computing (HPC) systems poorly represent the performance of science and engineering applications on the HPC systems. The most popular performance index of HPC systems, the TOP500, relies on a traditional LINPACK benchmark that is very limitedly used for modern HPC applications. The HPC community has recently made significant efforts to include more general numerical algorithms to represent the performance of modern HPC applications. This study is one of our continued efforts to find out the most optimal way to represent the performance of HPC systems and HPC applications [1,2,3]. We employed a high-order finite element application optimized for modern HPC systems to analyze performance characteristics depending on several configurations such as the order of shape functions, employed linear algebra solvers and structure for MPI and OpenMP hybrid computing. We profiled the application in scale with Cray Performance Measurement and Analysis Tools (CPMAT) on Blue Waters at National Center for Supercomputing Applications (NCSA). We present collected hardware counter data for flops, flop-rates, L1/L2/L3 data cache accesses and memory access for several important routines. In addition, we discuss potential rooflines of the system performance by analyzing the performance characteristics of the crucial routines for the considered configurations. With the above analysis, we provide our recommendations to help scientists and engineers optimize their algorithms for science and engineering applications on modern HPC systems. [1] J. Kwack, G. Numerical Simulation of Wave/Current-Induced Scour Below Pipelines Using RKPM Method

On Lei Annie Kwok*, Pai-Chen Guan**, Chien-Ting Sun***

*National Taiwan University, **National Taiwan Ocean University, ***National Taiwan Ocean University

ABSTRACT

Stability of marine pipelines and marine cables can be significantly affected by the presence of scour due to repeated wave and current action. In this study, RKPM (reproducing kernel particle method)-based numerical framework is used to simulate this fluid-structure-soil interaction process. Semi-Lagrangian reproducing kernel incompressible fluid method is employed to model the ocean wave and tidal flow while the pipeline is analyzed by RKPM Mindlin plate formulation. A non-cohesive seabed sediment is considered and modeled by a semi-Lagrangian reproducing kernel method. A contact algorithm is used to handle the interaction between fluid (waves), structure (pipelines) and solid (soil sediment). This investigation focuses on the effect of pipeline embedment, water depth to pipeline diameter ratios and soil properties on the stability of submarine pipelines/cables.

Method to Analyze Welding Deformation Based on a Visualization Model for Plant Construction

KiYoun Kwon*

*Kumoh National Institute of Technology

ABSTRACT

The ship and offshore plant are designed by dividing it into several blocks which constitute the hull, and each block is constructed separately and assembled. Blocks are usually made by assembling small parts fabricated by machining steel plates, and the plant is constructed through the assembly of large blocks from the small blocks. During these process, welding deformation causes many problems [1]. In order to prevent welding deformation, FEA (finite element analysis) is widely used. In this paper, we propose a mesh generation method to enable welding analysis based on a visualization model. The visualization model is widely used for visualizing and sharing large cad data in PLM (product lifecycle management) [2]. This model is mainly composed of triangular elements to minimize the file size and improve rendering performance. The method proposed in this paper is as follows. The visualization model has no information about the welding line. First, boundary curves are restored from the triangle elements of visualization model. After matching the connectivity of triangular elements, boundary element edges are extracted. Boundary curves are generated by connecting these boundary element edges. If the restored boundary curve lies on another part, it is classified as a welding line. Then, a polygon surface is created by using triangle elements constituting boundary curves for each plate, and a trim surface is created to include welding lines. The number of elements is given to the boundary curves and the welding lines, and a quadrilateral mesh is generated by using the domain decomposition method [3]. Finally, the welding line attribute information is added to the elements included in the welding line so that thermal deformation analysis is possible References 1. Hygroelastic Multiscale Modeling of Epoxy-based Nanocomposites

Sunyong Kwon*, Man Young Lee**, Seunghwa Yang***

*Chung-Ang University, **Agency for Defense Development, ***Chung-Ang University

ABSTRACT

Hygroscopic aging occurs inevitably by consistent exposure to moisture in service condition of epoxy-based nanocomposites. Slow and steady process of aging causes swelling, plasticization, and degradation of mechanical and interfacial properties of epoxy-based nanocomposite eventually leading to the fast fracture of nanocomposites. Since the aging is a long-time process, experimental approach of hygroscopic aging is burdensome because it needs accelerated aging environment accompanied by time-to-time preparation of epoxy coupons for evaluation of properties. Therefore, in order to access hygroelastic behavior with computational mechanics, molecular dynamics (MD) simulation is firstly applied. To determine the aged structure-to-hygroelastic property relationship of epoxy-based nanocomposite, varying cross-linking and water contents of diglycidyl ether of bisphenol F (EPON862®)/ triethylenetetramine (TETA) epoxy system is studied. A defect-free single layer graphene is added in the nanocomposite structure as reinforcement. The dynamic cross-linking method is used to set the crosslinking ratio of epoxy from 30 to 70%. For each cross linking ratio, moisture weight fraction of 0, 2, 4 wt% is considered in each nanocomposite unit cell. Through the classical ensemble simulation incorporated with ab-initio parameterized PCFF forcefield, coefficient of moisture expansion (CME), diffusion coefficient of water, and elastic modulus and cohesive zone law of epoxy/graphene nanocomposite models are predicted. To efficiently diagnose and predict hygroscopic aging in real life conditions, establishing ternary correlation of aging time-micro structure- macro property is necessary. However, as MD simulation can only describe couple microseconds of material status, continuum scale computational analysis with well-established time dependent property analysis is essential to overcome the limitations of MD simulation in describing hygroscopic aging behavior of epoxy-based nanocomposites. Furthermore, hygroelastic and interfacial properties of epoxy/graphene nanocomposite calculated by MD simulation are essential element for implementing multi-scale analysis. Therefore, MD simulation incorporated with micromechanics theory and finite element method (FEM) is presented in this study. Thus, based on the previous calculation of hygroelastic and interfacial properties by MD simulation, moisture expansion elastic constitutive equation model and stress-strain behavior of moisture absorbed nanocomposite constitutive equation model approximation can be developed. Also, mapping of elastoplastic properties by connecting time dependent moisture concentration profile and Young's moduli of epoxy-based nanocomposite will be analyzed.

ABSTRACT

The finite element discretisation of a large class of boundary value problems requires highly refined meshes to appropriately resolve, e.g., singularities in contact problems, shear bands in elasto-plasticity or steep local gradients in the field variables of phase-field models. If these domains evolve during the simulation, adaptive local mesh refinement and coarsening are essential for efficient computations. As Isogeometric Analysis (IGA) introduced by Hughes et al. [1] overcomes the disjunction between geometry and computational models it is the ideal discretisation technique to be combined with adaptive mesh refinement because already the coarsest mesh provides an exact geometry representation which is preserved during refinement. Tedious interactions with an underlying geometry during re-meshing, which is required to increase the accuracy of the geometry representation in standard FEM, are avoided. We present projection methods and transfer operations required for adaptive mesh refinement/coarsening in problems with internal variables at integration point level. By extending the results of Hennig et al. [2], we propose three different local and semi-local least squares projection methods for field variables and compare them to the standard global version. We discuss the application of two different transfer operators for internal variables. An alternative new operator inspired by superconvergent patch recovery [3] is also proposed. The presented projection methods and transfer operations are tested in benchmark problems and applied to phase-field modelling of spinodal decomposition and brittle and ductile fracture. ABSTRACT

Heart diseases are the leading cause of death in the western World. A deeper understanding of the heart functioning can provide important insights for medical doctors and clinicians in treating cardiovascular diseases but its extraordinary complexity represents a challenge for scientists and clinicians studying it. In this respect, some recent efforts have been made to be able to model the functioning of the heart along the entire heartbeat using the finite element commercial software LS-DYNA [1]. The model starts with Electro-Physiology (EP) which simulates the propagation of the wave of cell transmembrane potential in the heart. Different models, called “mono-domain” or “bi-domain”, couple the diffusion of the potential along the walls of the heart with ionic equations describing the exchanges between the inner and the outer parts of the cells. These models give in particular the local intracellular calcium ion which provides the activation part of the heart muscle myofilament models, hence the input for the mechanical tissue models. The mechanical deformations of the heart are coupled with the hemodynamics using the Fluid and Structure Interaction (FSI) model of LS-DYNA. Benchmarks of the different parts of the model will be presented, followed by coupled multiphysics simulations of parts of the heart as well as an example of a full heart beat. The model will also be used to show the difference between a healthy heart and different heart diseases such as cardiac arrhythmia, in term of EP behaviors, mechanical deformations and pumped blood. SIMNANO: A Highly Efficient Molecular Systems Energy Minimizer

NIKOS LAGAROS*, STAVROS CHATZIELEFTHERIOU**

*Institute of Structural Analysis & Antiseismic Research, School of Civil Engineering, National Technical University of Athens, **Institute of Structural Analysis & Antiseismic Research, School of Civil Engineering, National Technical University of Athens

ABSTRACT

In this study a new energy computationally highly efficient minimizer is presented, achieving excellent convergence properties; therefore, becomes suitable for dealing with large-scale molecular systems. SimNano relies on the analytical calculation of the gradient vectors and hessian matrices of the molecular systems by applying a computational modeling framework, possessed by the authors (J. Chem. Inf. Model. 2016, 56 (10), 1963-1978), that was inspired from structural mechanics and the finite element method. In order to present the efficiency of the proposed energy minimizer several test cases are examined and the results are compared with those obtained by one of the most popular molecular simulations software (LAMMPS). The comparative results indicate that the proposed minimizer depict superior convergence properties to those of the algorithms that are generally employed in the field. SimNano energy minimizer can be downloaded for free from the site: http://users.ntua.gr/nlagaros/simnano.html.

Optimization of Stiffened Composite Plate Using Artificial Neural Network-based Different Evolution Algorithm

THUAN LAM-PHAT*, Son Nguyen-Hoai**, Quan Nguyen-Anh***

*GACES, HCMC University of Technology and Education, Vietnam, **GACES, HCMC University of Technology and Education, Vietnam, ***GACES, HCMC University of Technology and Education, Vietnam

ABSTRACT

In this paper, a new algorithm called ABED (Artificial neural network Based Differential Evolution) is used to find the optimal design for the stiffened composite panel structure. This ABED algorithm is formed by the combination of an improved version of the Differential Evolution (DE) algorithm with the Artificial Neural Network technique and is adopted to look for suitable values of the fiber angle and the thickness of the stiffened composite plate. The ANN is used to compute the fitness of the object functions and evaluate the values related to the constraint conditions, meanwhile, the DE algorithm is used for optimization task. To verify the accuracy and the effectiveness of the algorithm, numerical solutions obtained from the proposed method are compared with those of other available approaches.

A Novel First-order Reliability Method Based on Performance Measure Approach for Highly Nonlinear Problems

Gang LI*, Bin Li**, Hao Hu***

*Dalian University of Technology, **Dalian University of Technology, ***Yancheng Institute of Technology

ABSTRACT

The first-order reliability method (FORM) is widely used in structural reliability analysis for its simplicity and efficiency. When searching the MPP in traditional FORM, gradient-based algorithms may fail to converge due to oscillation or chaos if the performance function is highly nonlinear. Evolutionary algorithms could achieve convergence solutions even for highly nonlinear performance function, usually with expensive computational cost. To overcome their drawbacks, we propose a new reliability analysis method called PMA-IACC to search the most probable failure point (MPP). As the inverse reliability analysis and reliability analysis are reversible each other, the performance measure approach (PMA) of the inverse reliability analysis could be used for the reliability analysis based on the multi-objective optimization theory. With the iterative calculation of performance measure, the approximate MPP and reliability index would be gradually close to the true MPP and reliability index. Furthermore, the improved adaptive chaos control (IACC) method is also proposed to further improve the robustness and efficiency of inverse reliability analysis by updating and choosing suitable chaos control factors, without additional computational efforts at each iteration. And then, the IACC is integrated into the PMA reliability analysis strategy. The proposed PMA-IACC method has outstanding performance, which has been illustrated by five highly nonlinear examples with different dimensions, distributions and local optimal solution. Compared with some traditional reliability analysis methods, the proposed PMA-based reliability analysis methods (PMA-MCC, PMA-ACC, PMA-IACC) always show better accuracy and efficiency, among which the PMA-IACC is the best and is beneficial to the application in complex engineering problems. Furthermore, although it is hard to obtain the exact probability of failure currently by our proposed method in frame of FORM, our current work could be further used for higher-order reliability analysis based on the MPP-based DRM in the future study.

Multiscale Modeling of Soft Contact and Imulation of Cell Motility

SHAOFAN LI*

*University of California-Berkeley

ABSTRACT

Experimental observations have shown that the elasticity of the extracellular substrate has significant influence on cell motility and cell rotation. To explain such bio-physical or physiology phenomenon has been one of focuses of cell biology or cellular mechanobiology. In this work, we shall discuss multiscale modeling and simulations of soft matter contact and cell adhesion. In particular, our work is focused on modeling and simulation of contact and adhesion of cell on substrates with different rigidities and micro-structures. We have developed a soft matter cell model for actin filament aggregate, and a coarse-grained contact model that is based on a recently proposed multiscale adhesion model, which can take into account the long-range Van der Waals force, steric force, and colloidal interactions etc. By modeling the cell as an isotropic amphiphilic aggregate, it may be shown that under external stimulus the cell can change its microstructure, conformation, as well as configuration. We have used the soft matter cell model, the multiscale cell adhesive and contact model in conjunction with recently proposed Multiscale Moving Contact Line theory to successfully simulate cell motility in a virtual environment.In this presentation, we shall present our latest results on numerical simulations of cell contact, adhesion, spreading, and self-moving.

Multiscale Crystal Defect Dynamics (MCDD): Towards an Atomistically Determined Crystal Plasticity via Multiscale Dislocation Patter Dynamics

SHAOFAN LI*, Dandan Lyu**

*University of California-Berkeley, **University of California-Berkeley

ABSTRACT

In this work, we present the latest development of multiscale crystal defect dynamics (MCDD) for modeling of crystal plasticity by simulating crystal defect evolutions at small scales. The main novelties of the proposed MCDD are: (1) We use the dual-lattice tessellation to construct a process zone model that can represent dislocation patterns in single crystal; (2) We adopt a fourth-order (four scales) hierarchical strain gradient theory to model constitutive behaviors of various dislocation patterns, in which the atomistic-informed higher order Cauchy–Born rule is employed, and (3) We employ the Barycentric finite element technique to construct finite element shape functions for polygonal and polyhedral process zone elements. The proposed MCDD method provides an efficient and viable alternative to both molecular dynamics (MD) and dislocation dynamics (DD) in simulations of defect evolutions such as dislocation nucleation, and growth. In particular, MCDD offers a mesoscale description for dynamic lattice microstructure, defect microstructure, and their interactions. The method offers a possible solution for studying nanoscale and mesoscale crystalline plasticity. In this approach, coarse-grained models are adopted for both bulk media and material interphase or process zone. In bulk elements, the first order Cauchy-Born rule is adopted, so we can formulate an atomistic enriched continuum constitutive relation to describe the material behaviors. All the nonlinear deformation is assumed to be confined inside the process zone, and the process zone between the bulk elements is remodeled as a finite-width strip whose lattice constants and atomistic potential may be the same or different from those of the bulk medium. Inside the interphase zone, the higher order Cauchy-Born rules are adopted in process zones, and a higher order strain gradient-like coarse grain constitutive model is derived, which can capture the size-effect at the small scales. All interphase or process zones are constructed such that they are part (a subset) of slip planes in a lattice space. The multiscale crystal defect dynamics has been applied to simulate both dislocation motion and crack propagations in both single crystals and polycrystalline solids. Crack branching and void formation have been found possible for different element mesh stacking fault energies, which are dictated, by the effective lattice structure or microstructure in the process zone elements.

Modified Inherent Strain Theory for the Metal Additive Manufacturing Process with Experimental Validation Using Embedded Optical Fiber

XUAN LIANG*, Albert To**

*University of Pittsburgh, **University of Pittsburgh

ABSTRACT

Additive manufacturing (AM) has been paid increasing attention over the past few years, since usually arbitrarily-shaped parts can be manufactured through a bottom-up approach with little geometric limitation. However, residual stress and distortion have been the most critical issue for metal AM process. It is important to give an accurate prediction of residual stress and distortion in order to guarantee the quality of the printed metal parts. Usually thermomechanical simulation is employed to calculate the residual stress and strain; however, it is too time-consuming to simulate the printing process of a metal part containing thousands of layers. The inherent strain theory was established for solving residual stress and distortion for simple welding problem. It has been proved that the original theory is not accurate for calculating the residual stress and strain of the metal AM process. Therefore, the modified inherent strain theory is proposed in this work, taking the detailed physical process of metal AM into consideration. The modified method considers two different states in the metal AM process. On the one hand, an intermediate state is concerned where rapid solidification occurs, and the plastic strain is extracted correspondingly as the first part of the inherent strains. On the other hand, the increment of the elastic strains of the intermediate and final state is considered to be the other source of the inherent strain. This source of the inherent strain indicates the influence of the changing mechanical boundaries due to the new depositions in the multi-layer printing process. Based on the two different contributions, the modified inherent strains can be obtained. To capture the two important states in the metal AM process, the embedded optical fiber is used to measure the strain distribution in real time. Based on the measurement, the modified inherent strains can be calculated. Uniform averaged inherent strains are applied to a layer in a macroscale geometrical model as equivalent coefficients of thermal expansion. Meanwhile, variation of the inherent strains as a function of the distance to the deposition substrate will be employed in the layer depositing direction. After all the inherent strains are loaded, unit temperature change is applied to the model. Through a one-time full-body static analysis, the residual stress and distortion can be predicted in short time. Compared with the experimental measurement, good accuracy of the modified inherent strain method has been validated, which shows great potential for application to the metal AM field.

Key words: Human middle ear, Vibration characteristics, Auditory ossicles, Columella.

Abstract. In this paper, investigation on vibration characteristics of the human middle ear was carried out using the finite element harmonic vibration analysis. It was clarified that there is a relationship between hearing ability and stapes displacement including frequency characteristics. In tympanoplasty, the linkage of auditory ossicles may be reconstructed using the column article called the columella. It was also confirmed that stapes displacement changes according to the shape of columella or its mounting position to malleus. Then, a new method is proposed for estimating the hearing restoration effect prior to the tympanoplasty operation. That is, the hearing restoration effect can be estimated by a comparison of the differences in the stapes displacement between the reconstruction model and a healthy subject. In this study, as a part of the optimum design of the columella with the aim of better sound conduction efficiency, the correlation of columella junction area to the auditory ossicles and hearing restoration effect was clarified.

1 INTRODUCTION

In 2012, the World Health Organization (WHO) reported that there are 360 million persons in the world (5.3% of the world's population) with disabling hearing loss [1], which is one of the most severe problems in usual life activity of the human being. Conductive hearing loss is the most common case due to problems in the middle ear or the outer ear at times. A human middle ear which includes auditory ossicles (malleus, incus and stapes) and the tympanic membrane is a mechanical system. A key function of the mechanical system is to transmit sound energy from the air into the inner ear. The audition process begins in the tympanic membrane, which receives sound energy from outside and this cases the membrane to vibrate. Then the vibrations are amplified by the auditory ossicles while being transmitted through the malleus, incus and stapes. Finally, The stapes is responsible for transferring the vibrations into the cochlea fluid of the inner ear so that the hair cells in the inner ear can generate the neuronal signals. The conductive

hearing loss occurs when the middle ear is damaged by various ear diseases, and sounds hardly transfer through the ear canal to the eardrum and three ossicles. The chronic otitis media or middle ear cholesteatoma in which the ossicular chain in middle ear is damag causes severe conductive hearing loss. The tympanoplasty operation is often carried out to reconstruct the damaged ossicular chain, and to improve the sound conduction efficiency. In the ossicular chain reconstruction, the column article called columella is produced and used instead of incus which is generally broken. In this operation, the sound conduction efficiency changes by the variations in the shape, material and mounting position of the columella. Currently, the operation is carried out based on the workmanship and experience of the surgeon. Identification of the dynamic characteristics of the middle ear is very important in many areas including hearing aids, hearing loss evaluation, and design of middle ear prostheses. Many experimental measurements have been conducted in order to understand the dynamics of the middle ear. H. Wada et al. measured Youngs modulus, thickness and damping ratio of the human eardrum by using measuring aparatus developed by themselves [2]. S. E. Voss et al. reported the Measurements on human cadaver ears that describe sound transmission through the middle ear [3]. R. Aibara et al. measured the middle-ear pressure gain in 12 fresh human temporal bones for the 0.05 to 10 kHz frequency range [4]. However, experiments on live humans and cadavers are very limited. The dynamic characteristics of the middle ear exhibit a very complex behavior as well as individual variations. Several researchers on middle ear system use finite element analysis (FEA) in their study. The FEA is a powerful tool to analyze the vibration of a middle ear because the middle ear has a complicated shape. As for dynamics analysis on the middle ear system, a cat eardrum was firstly investigated by a finite element analysis on the curved conical eardrum byW. R. I. Funnell and C. A. Laszlo [5]. After that, H. Wada et al. made a three-dimensional FEM model of a human right middle ear, which included ossicles and the mechanical properties and boundary conditions of the middle ear were determined by a comparison between the numerical results obtained and the measurement results [6]. R. Z. Gan et al. performed a three-dimensional finite element analysis of the human ear that included the external ear canal, eardrum, ossicular bones, middle ear suspensory ligaments/muscles, and middle ear cavity [7] [8]. Q. Sun et al. proposed a practical and systematic method for reconstructing accurate computer and physical models of entire human middle ear[9]. T. Koike et al. performed the finite element analysis of the human middle ear and compared calculated results with measurement data [10]. Moreover, Liu et al. carried out a three-dimensional finite element analysis of human ear in order to analyze lesion of ossicular chain [11]. Computational modeling methodology of multi-body system was examined in order to simulate and study the middle ear mechanical response to acoustic stimulus by F. Bohnke et al. [12]. D. D. Greef et al. performed dynamics analysis on a new anatomically-accurate model composed of the tympanic membrane and malleus using the finite element method [13]. Lee, D. and Ahn, T. S. proposed statistical calibration framework effectively improves the middle ear FE model performance [14]. Nevertheless, there are few studies regarding clinical applications and aiming at improvement of the sound conduction efficiency in tympanoplasty. As mentioned upon, in the tympanoplasty operation, the shape, material and mounting position of the columella have been decided based on the workmanship and experience of the surgeon. In this paper, we introduce a new numerical approach using the finite element harmonic vibration analysis for estimating the hearing restoration effect prior to the tympanoplasty operation. This kind of approach makes it possible to propose a new medical treatment for the recovery of conductive or cochlear hearing loss. Fist of all, precise geometric models of the middle ear, including healthy type model and tympanoplasty type models, were

constructed on the basis of the computerized tomography (CT) scanning data. Then, frequency response characteristics of the stapes displacement in sound conduction were clarified using three-dimensional finite element harmonic vibration analysis. The vibration analysis was also carried out to investigate the effect on the frequency response characteristics caused by changes in the characteristics of the annular ligament and the division of the tympanic membrane. Based on the investigation results of vibration characteristics of the human middle ear, we proposed that the hearing restoration effect can be estimated by a comparison of the differences in the stapes displacement between the recon struction model and the healthy subject. As an application for clinics in tympanoplasty, four kinds of models that change the mounting location of the columella were analyzed in order to investigate the difference of the dis placement of the stapes basal plane. By comparing those analytical results with the result for a healthy model as a standard, the possibility of a clinical application of our method has been verified. Furthermore, as a part of the optimum design of the columella with the aim of better sound conduction efficiency, the correlation of columella junction area to the auditory ossicles and hearing restoration effect was clarified.

2 THE HUMAN MIDDLE EAR AND ITS FUNCTION

Figure 1 shows the structure of the ear. The middle ear is composed of the tympanic membrane, tympanic cavity, auditory ossicles and others. Auditory ossicles are behind the tympanic membrane in a small space (tympanic cavity), and they are composed of malleus, incus and stapes. The stapes basal plane connects with the inner ear through an oval window.

The tympanic cavity is a space filled with air. The inner wall of the tympanic cavity is covered with a mucous membrane. The air pressure of the tympanic cavity is controlled at the appropriate value by ventilation in order to keep the important function that is the sense of hearing. Furthermore, the tympanic cavity has a washing function that absorbs and removes bacterial waste by the secretion and reabsorption of the mucus. Each part of the auditory ossicles is connected with the joints. They are suspended by ligaments and muscles in the tympanic cavity. The vibration amount of the tympanic membrane is amplified about 17 times by the area ratio of the stapes basal plane and the tympanic membrane. In addition, the vibration amount of the tympanic membrane is amplified about 1.3 times by the lever motion of the auditory ossicles.

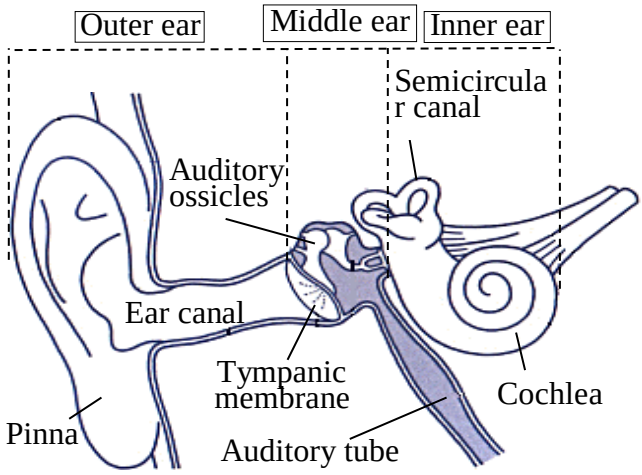

Fig. 1 Structure of the human ear

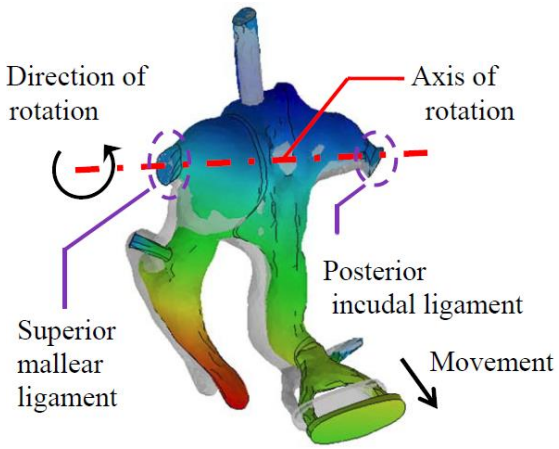

Fig. 2 Deformation of auditory ossicles

Figure 2 shows that the auditory ossicles turn about the axis connecting the superior ligament and the posterior incudal ligament [15]. By this rotary motion, the vibration of the tympanic membrane is efficiently converted into *Z*-direction (perpendicular to the stapes basal plane) movement of the stapes. The stapes vibration is transmitted to the labyrinthine fluid of the internal ear and converted to electrical signals, which are then recognized as sound in the brain. In this study, we consider that there is a certain relationship between hearing ability and the *Z*-direction displacement of the stapes.

3 GEOMETRIC MODELING OF THE MIDDLE EAR

The precise geometry of ossicles was obtained through CT scanning of the human head. As shown in Fig. 3, the two-dimensional slice images of the CT scanning data were transformed into three-dimensional solid geometries using a post-processing software and the region which contains the three ossicles was separated from the CT scanning data. Then, the 3D geometries were refined and converted to DICOM data, and further converted into STL data, which were imported into a general-purpose structure analysis software to create a FEM model. The geometric model for a healthy subject for finite element harmonic vibration analysis is shown in Fig. 4. This model is composed of the tympanic membrane, auditory ossicles, ligaments, joints, stapedial muscle and others.

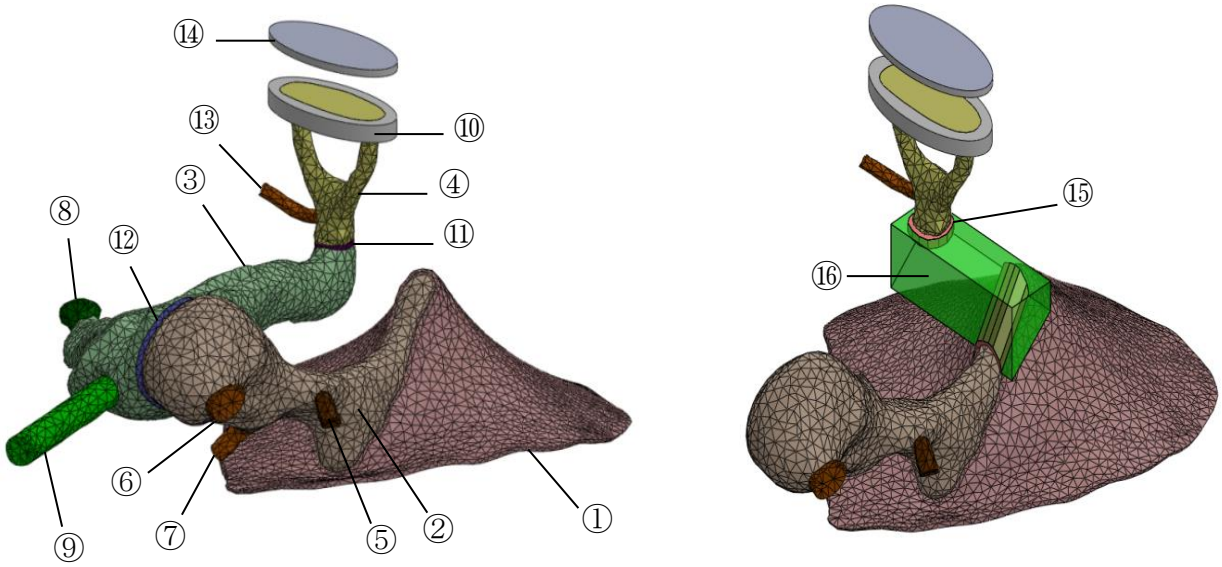
4 HARMONIC VIBRATION ANALYSES

4.1 Material data

Material data of the analysis model are shown in Table 1 [9] [10] [17]. The anatomical parts name number in the table corresponds to the number in Fig. 4. The base plate 14 is a virtual part for supporting the spring. Therefore, its Young's modulus can be assumed to be that of a rigid body.



(a) Healthy subject model of middle ear (b) Operation model of middle ear

Fig. 4 Model of middle ear

Table 1 Material data

Anatomical name	Young's Modulus（MPa）	Density（kg/m^3）	Poisson's ratio
①Tympanic membrane	33.4	1,200	0.3
②Malleus	13,436	4,350	
③Incus			
④Stapes			
⑤Lateral mallear ligament	21	2,500	
⑥Superior mallear ligament			
⑦Anterior mallear ligament			
⑧Posterior incudal ligament	0.65		
⑨Superior incudal ligament			
⑩Stapedial annular ligament			
⑪Incudostapedial joint	6	1,200	
⑫Incudomallear joint			
⑬Stapedial muscle	0.52	2,500	
⑭Base plate	1×10^{10}	-	
⑮Columella（joint）	6	1,200	
⑯Columella（Main body）	112,400	2,330	0.28

4.2 Boundary conditions

The tympanic membrane circumference, edges of ligament and muscle, and base plate were perfectly fixed in load conditions. A sound pressure of 90dB was converted into pressure using the equation (1) as load conditions.

$$L_p=20\log_{10}(P/P_0) \quad (1)$$

In Eq. (1), L_p = 90dB is the setting sound pressure (a relative noisy level) and $P_0 = 20\times10^{-6}$Pa a standard value (the lowest value of the sound intensity which is audible for humans). As a result, a pressure of P=0.632Pa was obtained. However, in this analysis, P=15.2Pa was given at the contact surface of the tympanic membrane and malleus. The ratio 15.2/0.632 equals the ratio of the total area of the tympanic membrane to the contact surface area of the tympanic membrane and malleus. A spring of 40N/m spring constant was installed between the stapes and the base plate referring to the research of Gan et al [8]. Rayleigh damping was assumed and damping factors of α=0s^{-1}, β=7.5×10^{-5}s.

4.3 Finite element analysis results of the healthy model

In this research, harmonic vibration analysis was done as a dynamic analysis using the finite element method. Fig. 5 shows the harmonic vibration analysis results for a healthy subject. The longitudinal axis shows the displacement of the stapes bottom in a perpendicular direction to the basal plane, and the lateral axis represents the frequency. In cases of a healthy subject, it is said that there is a resonance region of the middle ear at 0.5~2 kHz in frequency, that is, conversation range. Average displacement of the stapes basal plane shows the peak of the resonance to be near 1.3 kHz in frequency in the analytical results for a healthy subject. This displacement decreases gradually with an increase in frequency over 2 kHz. It is possible to reproduce the resonance phenomena to some extent by our finite element model. Fig. 5 shows that the average displacement of the stapes base for the sound pressure of 90dB is 5.09×10^{-6} mm, which was used as a standard value in this study. If the change in this displacement is compared, the hearing restoration effect can be estimated prior to the tympanoplasty operation, in the case where the medical device, called columella, is substituted for the deficient auditory ossicles, or in the case of stiffening of the ligament. This kind of approach makes it possible to propose a new medical treatment for the recovery of conductive or cochlear hearing loss.

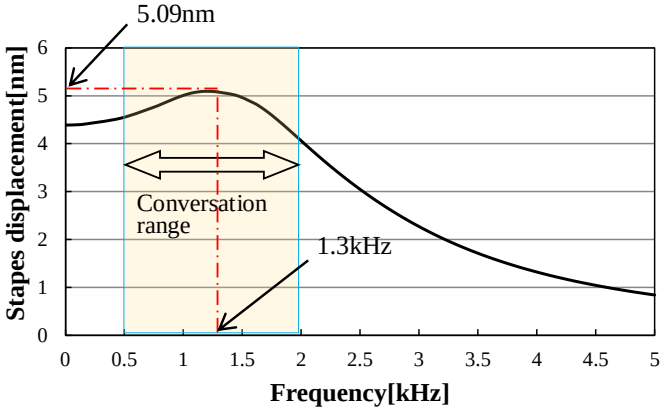


Fig. 5 Frequency response graph of healthy subject model

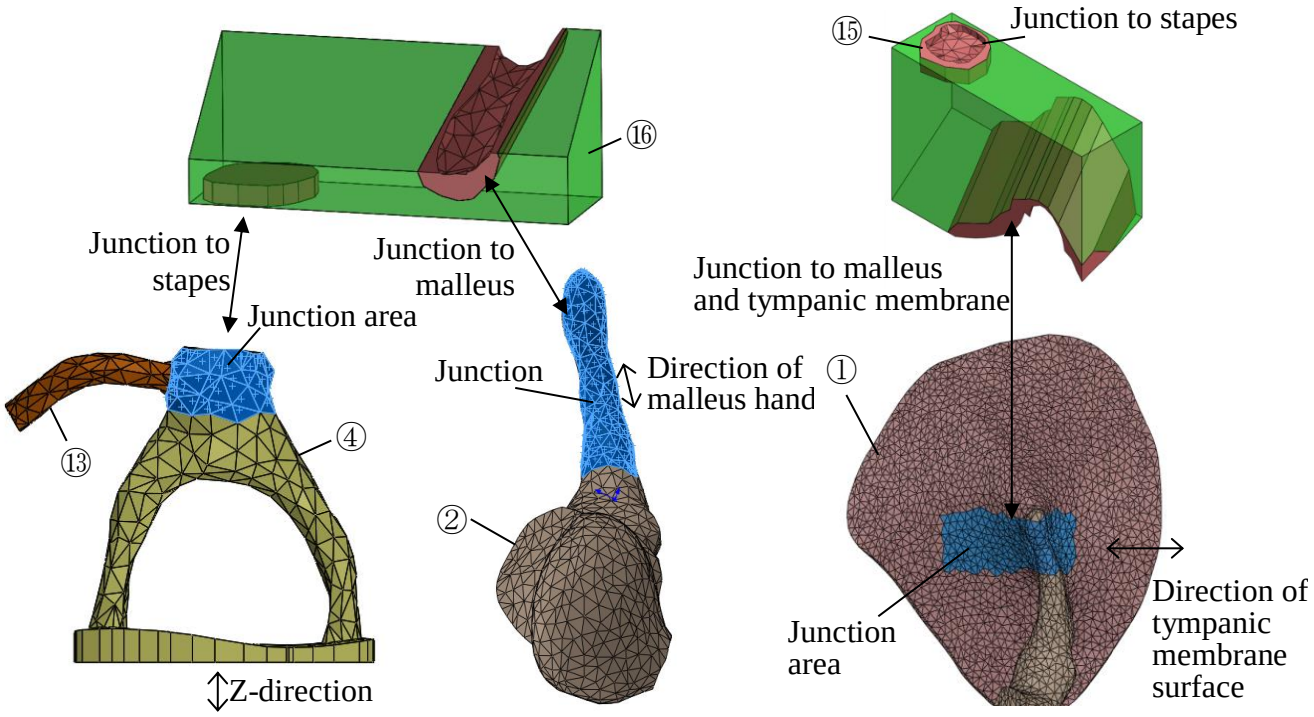
5 APPLICATION FOR CLINICS IN TYMPANOPLASTY

As mentioned in Section 1, the tympanoplasty operation is often carried out to reconstruct the damaged ossicular chain to improve the sound conduc tion efficiency when auditory ossicles were damaged for chronic otitis media, etc.. In the ossicular chain reconstruction, as shown in Fig. 4(b), the column article called columella is produced and used instead of incus which is generally broken. As a part of the optimum design of the columella with the aim of better sound conduction efficiency, the correlation of columella junction area to the auditory ossicles and hearing restoration effect was studied.



(a) Junction area for the stapes (b) Junction area for the malleus (b) Junction area for the tympanic membrane

Fig. 6 Definition of the junction area

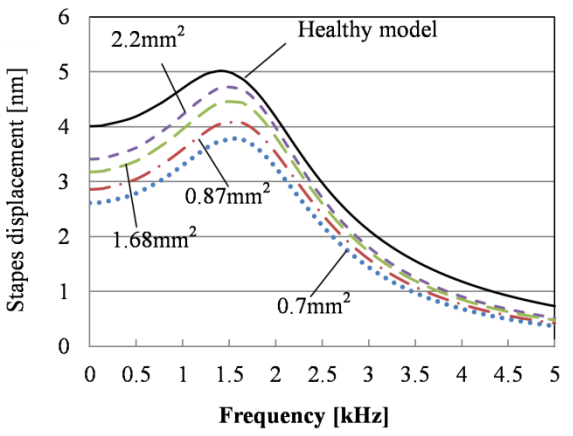


Fig. 7 Frequency response graph for the Fig. 6(a) model

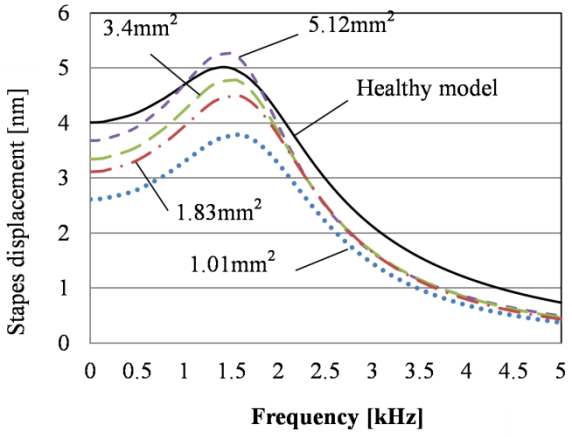

Fig. 8 Frequency response graph for the Fig. 6(b) model

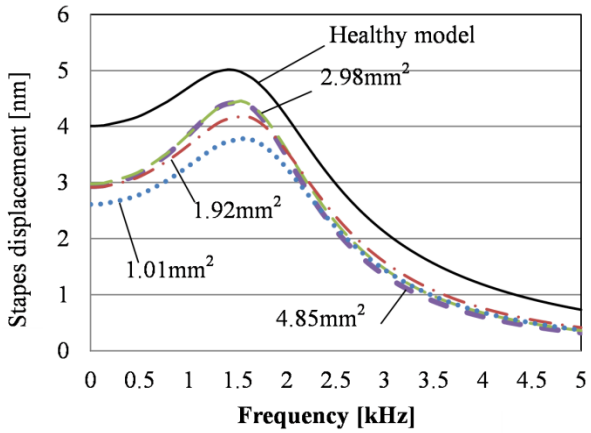

Fig. 9 Frequency response graph for the Fig. 6(c) model

The junction area is the contact area between a columella and malleus, stapes or tympanic membrane. The junction area is changed by the change of shape of the columella. A standard model of columella is shown in upside of Fig. 6. The junction area for the stapes side is shown in Fig. 6(a). In the case of stapes side, the shape of the columella is changed in the *Z*-direction, which is perpendicular to the basal plane of stapes. The junction area for the malleus side is shown in Fig. 6(b). In the case of malleus side, the shape of the columella is changed in the direction along the handle of malleus. The junction area for the tympanic membrane side is shown in Fig. 6(c). In the tympanic membrane side, the shape of the columella is changed in the direction along the tympanic membrane surface. The number of ①, ②, ④, ⑬, ⑮, ⑯ in Fig. 6 corresponds to the number in Fig. 4 and Table 1. The influence by the change of the junction area is examined, and the correlation of hearing restoration effect and junction area is clarified.

A frequency response graph obtained by the finite element analysis is shown in Fig. 7~9. These figures show the relation between the normal displacement of stapes bottom and frequency. Figure 7 shows the results in case the junction area for the stapes side changes. The solid line shows the result for a healthy subject, and the dotted line shows the result for the model where the junction area equals 0.7mm^2. Moreover, the dashed and single-dotted line is the result for the model where the junction area is 0.87mm^2. The long dashed line is the result for the model where the junction area is 1.68mm^2.The short dashed line is the result for the model where the junction area is 2.2mm^2.

Figure 8 shows the results in case the junction area for the malleus side changes. The solid line shows the result for a healthy subject. The dotted line shows the result for the model where the junction area equals 1.01mm^2. The dashed and single-dotted line is the result for the model where the junction area is 1.83mm^2. Long dashed line is the result for the model where the junction area is 3.4mm^2. The short dashed line is the result for the model where the junction area is 5.12mm^2.

Figure 9 shows the results in case the junction area for the tympanic membrane side changes. The solid line shows the result for a healthy subject. The dotted line shows the result for the model where the junction area equals 1.01mm^2. The dashed and single-dotted line is the result

for the model where the junction area is 1.92mm^2. The long dashed line is the result for the model where the junction area is 2.98mm^2. The short dashed line is the result for the model where the junction area is 4.85mm^2.

Figures 7 and 8 show that the stapes displacement increases with the increase of junction area between auditory ossicles (stapes or malleus) and the colemella. By increasing the junction area, it is possible to more firmly connect the columella. Therefore, it seems to improve the transfer efficiency of sound. Fig. 9 shows that the stapes displacement increases with the increase of junction area between tympanic membrane and columella, but there is a limit in the increase. Tympanic membrane is not suitable to transmit the force, because the Youngs modulus of the tympanic membrane is considerably lower than that of auditory ossicles as shown in Table 1. In previous research [16], we have obtained the same results in static analysis. The vibration of the tympanic membrane cannot sufficiently transmit to the stapes due to its low rigidity.

6 CONCLUSIONS

The vibration characteristics of the human middle ear were investigated in this paper and were applied to improve the sound conduction efficiency in tympanoplasty. We have proposed that the hearing restoration effect can be estimated by comparison of the displacement of stapes basal plane prior to the operation. The validity of our proposal was confirmed by analyzing various types of operation models using harmonic vibration analysis and compared with a healthy subject. Furthermore, as a part of the optimum design of the columella with the aim of better sound conduction efficiency, the correlation of hearing restoration effect and junction area of the auditor ossicles was clarified. It is possible and important to optimize the columella from the engineering viewpoint using the finite element method. This kind of approach makes it possible to propose a new medical treatment for the recovery of conductive or cochlear hearing loss.

Fracture Mechanism for Porous Single Crystals under Various Stress States

ZHIGANG LIU*

*IHPC

ABSTRACT

Void growth and coalescence are well known as the main mechanism of ductile fracture. While less effort has been devoted to investigating the process of void growth and coalescence in single crystal. This work examines the onset of void coalescence, the void behaviors that often precede eventual failure in ductile porous single crystal. The occurrences depends largely on the stress states in the solid, characterized by the stress triaxiality (T) and the Lode parameter (L). In employing a 3D unit cell simulation with crystal plasticity constitutive model, the strain at onsets of void coalescence behaviors can be operationally defined for different crystal orientation. Validated against known experimental and numerical works, we have demonstrated the stress state dependence of void coalescence. The crystal orientation and stress states on void coalescence are studied with five original single crystal orientations and two initial void volume fractions.

ABSTRACT

In this study, a stochastic geometric nonlinear analysis of functionally graded (FG) shallow arch is investigated. The constitutive material composition of the FG arch varies along the radial direction of the cross section, so the mechanical performance of the arch can be well controlled for various engineering design purposes. Based on the Euler-Bernoulli hypothesis, both geometric linear and nonlinear analytical solutions of the structural responses (i.e., displacements, axial compressive force and bending moment) of the FG arch subjected to uniform distributed load are derived by using the virtual work method. The boundary condition of the investigated FG arch is identified as pin-ended support at both ends. By adopting the derived analytical solution, the relationship between the structural response and the various FG material properties can be analysed efficiently. Once the analytical solutions of the deterministic structural responses of the FG arch are established, the stochastic analysis of the FG arch structure is performed by direct Monte Carlo simulation method. Both uncertain material properties and loading conditions can be incorporated within the simulative analysis framework. One numerical example is presented to demonstrate the applicability and effectiveness of the proposed nondeterministic analysis framework for the geometric nonlinear analysis of FG arch structures.

Computational Investigation of Bio-inspired Composite Nano Rotor Blade

Zhen LIU*, Chen BU**, Shanyong ZHAO***

*State Key Laboratory for Strength and Vibration of Mechanical Structures, school of Aerospace, Xi'an Jiaotong University, **State Key Laboratory for Strength and Vibration of Mechanical Structures, school of Aerospace, Xi'an Jiaotong University, ***State Key Laboratory for Strength and Vibration of Mechanical Structures, school of Aerospace, Xi'an Jiaotong University

ABSTRACT

At ultra-low Reynolds number, the propulsive performance of nano rotor drops dramatically, which has a profound impact on the flight performance of NAV. The bio-inspired blade motion is introduced to improve the performance of nano rotor. However, the complex flow interacts with the flexible composite blade structure resulting in the variation of propulsion performance of nano rotor and the vibration of blade structure. In this paper, the nano-scale composite rotor with blade-pitching motion was studied computationally with a computational solvers based on a preconditioned compressible NS equations, Roe-scheme, LUSGS-?ts dual-time marching method coupling with a finite element solver. A non-contact modal experimental platform was established using sound excitation instrument and laser vibrometer. The structural characteristics of the composite nano rotor were measured. It was found that the natural frequencies are very close for the first two orders. The finite element model of composite rotor was created accordingly. The modal was studied computationally with FEM solver. It was found that the simulation results matched well with the experimental results which verified the correctness of the finite element model. The CFD model was established and the propulsive performance of nano rotor without bio-inspired motion was studied, respectively. The results showed that the computational results from Fluid-structure solver matched better than that for CFD solver. It is indicted that the fluid-structure method has a higher precision for nano rotor simulation. It is evident that it is necessary to consider the flexibility of the composite nano rotor when investigating the propulsion performance of bio-inspired nano rotor. Then the flow field of flexible nano rotor was also analyzed at different bio-inspired pitching frequency and the response of blade structure was also studied with the fluid-structure solver. Results showed that the propulsive performance for bio-inspired pitching rotor at different pitching frequency. It was found that the thrust and torque for the bio-inspired pitching rotor are higher than those for the rotor without bio-inspired motion. And it was also found that the propulsive performance for the nano rotor with bio-inspired pitching frequency of two times of that rotation frequency is higher than that with only one times pitching frequency. It is evident that the improvement enhanced with the increase of the pitching frequency. And the blade structure was also found vibrate with a small amplitude. In general, it was found that the bio-inspired pitching motion can improve the performance of nano rotor.

Multibody Dynamics to Build a Reduced Ordered Model of a Car Crash Simulation

Tanguy LOREAU*, Philippe SERRE**, Laurent NOYELLE***, Jean-Luc DION****

ABSTRACT

Finite element models for vehicle crash studies are unsuited for upstream design: they have a large number of degrees of freedom and require precise information. Furthermore, their complexity implies high computational costs that make them unusable for short optimization loops. A way to overcome this complexity is to adapt results from another finite element simulation or crashtest of a vehicle close to the one to design. But this process uses only one part of the knowledge of the company, which restrains the new vehicle to be close to the previous one and requires a long time modeling and calculation making it a bad candidate for optimization. In this study, we aim to build a fast computing and robust model from all the knowledge of the company on crash simulation. A first approach is to apply a well suited and designed reduced ordered model method (POD, PGD, Deep Learning) on the simulation database. Yet these methods all have weaknesses that make them unusable for the crash reduction: either they need a quantity of data the company can’t provide, or they are not adapted in contact detection, or the produced model needs parameters that are not available in upstream phases and, in all cases, these methods don’t relate about physics so the model can’t be so much extrapolated. A second approach, which is presented in this work, is to see a car during a crash as a rigid multibody system articulated with dissipative links (Carvalho & Ambrosio, 2011, Development of generic road vehicle multibody models for crash analysis using an optimization approach, International Journal of Crashworthiness). Indeed, an energetic analysis of a crash simulation shows that a very small quantity of parts explains most of the phenomenon. These parts can be modeled as sets of rigid bodies articulated with plastic links which localization and rheological parameters come from the finite element simulation. The method presented here proposes a way to read finite element simulations to soundly place sensors on finite element models and then, after a new simulation, to get rheological parameters and positions of links to build a multibody model from a finite element simulation. This new multibody model, after a well suited correlation and validation, will represent a car crash simulation.

The Magneto-electric Coupling in Multiferroic Composites: Magnetostrictive Preisach and Ferroelectric Switching Model

Matthias Labusch*, Jörg Schröder**

*University Duisburg-Essen, Germany, **University Duisburg-Essen, Germany

ABSTRACT

Multiferroic materials combine two or more ferroic properties and can exhibit an interaction between electric polarization and magnetization. This magneto-electric (ME) coupling can find applications in sensor technology or in magneto-electric data storage devices. Since most ME single-phase materials show such a coupling far below room temperature, the manufacturing of two-phase composites, consisting of a ferroelectric matrix with magnetostrictive inclusions, becomes important. Due to the interaction of both constituents the composites generate a strain-induced ME coupling at room temperature, where we distinguish between the direct and the converse ME effect. The direct effect characterizes magnetically induced polarization, where an applied magnetic field yields a deformation of the magnetostrictive phase, which is transferred to the ferroelectric phase. Due to the electro-mechanical properties of the matrix material the composite exhibit a change in polarization. On the other hand, the inverse ME effect characterizes electrically induced magnetization. The ME coupling significantly depends on the microscopic morphology and the ferroic properties of the individual constituents. In order to take both aspects into account, a finite element (FE^2) homogenization approach is performed, which combines via a scale bridging the macro-and microscopic level [1]. Thereby, the microscopic morphology is characterized by representative volume elements and the ferroic properties of the phases are described by suitable material models. The typical ferroelectric hysteresis curves are modeled by considering the switching behavior of the spontaneous polarizations of barium titanate unit cells [2], whereas the magnetic hysteresis loops are described by a Preisach operator [3]. [1] J. Schröder, M. Labusch, and M.-A. Keip: Algorithmic two-scale transition for magneto-electro-mechanically coupled problems – FE^2-scheme: Localization and homogenization. ABSTRACT

The optimal design in 3D of new electrical components from commercially available high-temperature superconductors pushes the limits of current computational tools. Strong currents develop near the envelope of the superconductor and under AC, the nonlinear resistance induces sharp fronts in the currents and in the magnetic field density. These are challenges for finite element approximations but they also introduce subtle regularity issues recently identified by our group. In this presentation, we discuss the a posteriori error estimation of the critical-state model from applied superconductivity, both with and without linearization. We also review our work on the generation of diffusion, and energy loss, at the front and its approximation by both FE approximation and non-oscillatory approximations using a relaxation formulation of the problem. Regularity issues at the boundary are further related to error estimation and modeling.

Spectral Analysis of the Deflated Complex Shifted Helmholtz Operator

Domenico Lahaye*, Kees Vuik**

*DIAM / TU Delft, **DIAM / TU Delft

ABSTRACT

The complex shifted Laplacian is widely recognized as a computationally very efficient preconditioner for the Helmholtz equation. It introduces a sequence of damped wave propagation problems. The linear systems that arise can efficiently be solved by for instance multigrid methods. This method can however be significantly accelerated by a procedure published in [1]. In this procedure, the preconditioner is multiplied with a deflation operator that employs multigrid vectors. The deflation operator thus accelerates the convergence of the preconditioner in a similar way that a coarse grid correction operator accelerates the convergence of a smoother in a multigrid method. The objective of this work is to analyze how damping influences the efficiency of the new hybrid method. We are especially interested in large amounts of damping that facilitates the approximate inversion of the preconditioner. Without the use of deflation operator, the converge of the outer Krylov method rapidly deteriorates with the amount of damping introduced. To study the influence of the deflation operator, we analyze the spectrum of the discrete Helmholtz operator preconditioned by a multiplicative combination of the first deflation operator and subsequently complex shifted Laplace preconditioner. We perform a Rigorous Fourier modal analysis of a one-dimensional model problem in which the Helmholtz equation with homogeneous Dirichlet boundary conditions discretized by a second order finite difference scheme on a uniform fine and coarse grid. With these choices, the discrete Helmholtz operator, the complex shifted Laplacian and the coarse grid operator share a set of eigenmodes. Our spectral analysis reveals that the inversion of the near-singular coarse grid operator causes the eigenvalues of the deflated operator spreads in tails along both sides of the real axis. The subsequent action of the preconditioner is to shrink, rotate and shift the set of eigenvalues. Unlike the case in which merely the preconditioner is employed, the smallest eigenvalue remains bounded away from zero for larger values of the damping parameter. Numerical results show that the eigenvalue distribution and the GMRES number of steps are well correlated. A much larger damping parameter than in algorithms without deflation can be used. This holds great promises for the future application of the new method. [1] A.H. Sheikh, D. Lahaye, L. Garcia Ramos, R. Nabben and C. Vuik, Accelerating the shifted Laplace preconditioner for the Helmholtz equation by multilevel deflation, Journal of Computational Physics, 322: 473--490, 2016.

Phase Field Modelling of Brittle Fracture in Thin Shells Accounting for Cracks Partly Through the Thickness

Wenyu Lai*, Jian Gao**, Yihuan Li***, Marino Arroyo****, Yongxing Shen*****

*University of Michigan-Shanghai Jiao Tong University Joint Institute, Shanghai Jiao Tong University, Shanghai, China, **University of Michigan-Shanghai Jiao Tong University Joint Institute, Shanghai Jiao Tong University, Shanghai, China, ***University of Michigan-Shanghai Jiao Tong University Joint Institute, Shanghai Jiao Tong University, Shanghai, China, ****Laboratori de Calcul Numeric, Universitat Politecnica de Catalunya, Barcelona, Spain, *****University of Michigan-Shanghai Jiao Tong University Joint Institute, Shanghai Jiao Tong University, Shanghai, China

ABSTRACT

In this work, we present a phase field fracture model for the brittle fracture of the Euler-Bernoulli beam theory and the Kirchhoff-Love shell theory under the principle of minimum potential energy. To account for transverse part-though cracks, we employ an ansatz for the phase field using two scalar fields within cross section, allowing variation of the phase field through the thickness. The problem then reduces to a one-dimensional nonlinear differential equation for the beam problem, or a two-dimensional nonlinear differential equation over the mid-surface for the shell problem, which can be solved with the finite element method. Combined with a phase field model discriminating tension and compression, this special treatment permits simulating fracture due to bending loads and to membrane loads. The continuous formulation then can be discretized using any standard numerical method allowing H^2 continuity of the basis functions. In the presentation, we will talk about efficient simulation schemes for the numerical algorithm.

Modelling and Numerical Algorithm for Contact Problems with Frictional Heat Generation and Wear in Peridynamics

Xin Lai*, Lisheng Liu**

*Wuhan University of Technology, **Wuhan University of Technology

ABSTRACT

For multi-body contact problems, accurate modelling and numerical algorithm of the contact interaction between objects are very important to ensure the reliability of the numerical simulation. Especially, the frictional heat generated in the sliding and contacting progress, which is usually neglected, has great effect on the behavior of the material and the structure in material cutting, wearing, and impact problems. In such circumstances, the dramatic increasing of temperature caused by the frictional heat may change the physical properties, mechanical properties, or even the states of the material. Therefore, Frictional heat should be considered when dealing with high-speed contact problems. In this work, contact interactions including frictional heat has been modelling and numerically implemented in Peridynamic framework, which is recently widely used in impact damage problems. Numerical examples are carried out to validate the validity and accuracy of our algorithm. Comparisons have been made to show the influence of the material behavior affected by the frictional heat.

Dispersion, Spurious Reflections and Spurious Bifurcation of Flexural Waves

José Laier*

*Engineering School of São Carlos USP

ABSTRACT

Wave velocity dispersion, spurious bifurcation (numerical instability) and spurious reflections of the flexural wave model produced by numerical integration were investigated [1]. Classic cubic beam finite elements of two nodes with consistent mass matrix are taken into account [2]. The Newmark average acceleration integration method of single step is used for integration in time. The resultant system of difference equation is then analytically integrated in non-finite terms (numerical wave solution) using complex notation. Numerical results reveal that even for refined mesh the spurious reflections can be significant.

A Positive Asymptotic Preserving Scheme for Linear Kinetic Transport Equations

M. Paul Laiu*, Martin Frank**, Cory Hauck***

*Oak Ridge National Laboratory, **Karlsruhe Institute of Technology, ***Oak Ridge National Laboratory

ABSTRACT

We present a new positive and asymptotic preserving numerical scheme for solving linear kinetic transport equations. The proposed scheme is developed based on the standard spectral angular discretization and the classical micro-macro decomposition. The three main ingredients of the proposed scheme are a semi-implicit time discretization, a dedicated finite difference space discretization, and positivity limiters. We show that the proposed scheme is asymptotic preserving in the sense that when the mean free path of the particles goes to zero, the scheme achieves a correct numerical scheme for the limiting diffusion equation, without restrictive time step constraints. We also prove that the proposed scheme preserves positivity of the spatial particle concentration in the solution, which fixes a common defect of spectral angular discretizations. The proposed scheme is tested on two benchmark problems on a two-dimensional spatial domain, one with a single material and one with two types of material embedded as a checkerboard.

*Earthquake Research Institute, The University of Tokyo, **Earthquake Research Institute, The University of Tokyo, ***Dept. of Civil Eng., The Univ. of Tokyo, ****Dept. of Humanities, Social and Political Sciences, ETH

ABSTRACT

We present the details of implementation and applications of an HPC enhanced Agent Based Model (ABM) for simulating tsunami triggered evacuation of large coastal regions. In seeking various strategies to accelerate evacuation process, quantitative evaluation of their effectiveness, identifying unforeseen problems, etc., numerical simulations are invaluable to disaster mitigation authorities. Simple queue models with 1D networks are widely used for mass evacuations due to the ease of use, limited of computer resources, etc. These simplified models are inadequate for studying certain scenarios in congested urban regions which demand the use of accurate high resolution model of environment and complex models of individuals. Some of the scenarios requires best use of the available narrow spaces, debris, visibility in night time, pedestrian-vehicle interactions, etc. With the aim of simulating such demanding scenarios, we developed an ABM which includes a high resolution model of environment and sophisticated agents capable of perceiving the environment in high resolution [1, 2]. Environment is modeled as a hybrid of high resolution grid and a graph which contains the topological connectivity of accessible spaces in the grid. Each agent scans its surrounding in the grid in high resolution mimicking the eyes of an evacuee. This allows them to perceive dynamic changes in environment like progression of inundation and act accordingly. Agent store their experiences with reference to the topological graph and use those information in decision making. In order to meet the high computational demand of sophisticated agents in high resolution environment, we implemented MPI+OpenMP hybrid HPC extension. The heterogeneous nature of agents, the movements of agents from the domain of one CPU to other, etc. give rise to significant load imbalance among CPUs. To cope with this load imbalance, we implemented a dynamic load balancer using the measured execution time of each agent as a heuristic.

A Multiscale and Multiphase Model for the Description of Paracetamol-induced Hepatotoxicity Using the Example of the Human Liver

Lena Lambers*, Navina Waschinsky**, Tim Ricken***

*Institute of Mechanics, Structural Analysis, and Dynamics; University of Stuttgart, **Chair of Mechanics, Structural Analysis, and Dynamics; TU Dortmund University, ***Institute of Mechanics, Structural Analysis, and Dynamics; University of Stuttgart

ABSTRACT

The liver is the most important human organ responsible for metabolic homeostatis. A further central task of the human liver is the detoxification of the blood since toxic substances or excessive medication can cause damage in the liver structure which can lead to acute liver failure. One example for a medicine which can cause hepatotoxicity is the analgesic Paracetamol (Acetaminophen).The toxic metabolites of the Paracetamol are normally bound by the internal Glutathione. When the concentration of Glutathione is exhausted, the metabolites react with cellular proteins causing liver necrosis. The detoxification capability of the liver can be affected by several liver diseases, e.g. the non-alcoholic fatty liver disease (NAFLD). The developed model is an extension of a previos published work, where a multicomponent, poro-elastic multiphasic and multiscale function-perfusion approach based on the Theory of Porous Media (TPM), see [1], [2] has been presented, cf. [3]. Additionally, the decomposition of toxic metabolites causing cell damage is supplemented using the example of Paracetamol. Since the liver has a complex structure and different sizes, a scale bridging approach is requested. The total organ consists of liver lobules, where the toxic metabolites, just like other nutrients and substances, are initiated into the liver with an anisotropic blood flow via the sinusoids. As the structure of the lobules is extremely complex, we use a multicomponent mixture theory based on the Theory of Porous Media (TPM) see [1], [2] to describe the lobule scale. The computational model consists of a tetra-phasic component body, composed of a porous solid structure, fat tissue with the ability of growth, a liquid phase representing the blood and a solid phase, which characterizes the necrotic cells. The phases consist of a carrier phase, also called solvent, and solutes, representing microscopic components, solved in the solvent and consisting of the nutrients responsible for the liver metabolism. The metabolism takes place in the liver cells, which are located along the sinusoids. To calculate the metabolism processes on the cell scale, an embedded set of coupled ordinary differential equations (ODE) is used. [1] De Boer, R. Deep Learning for Protein Structure Prediction and Protein Folding

Guillaume Lamoureux*

*Concordia University

ABSTRACT

I will be presenting our recent progresses on the development of deep neural networks for the prediction of the structure of a protein from its amino acid sequence. We are interested in neural network architectures that mimic the protein folding process and that learn not only the native structure of a protein but the shape of the folding funnel leading to it. In particular, we use neural networks designed to respect translational and rotational invariance, and to generate structures that obey the rules of molecular folding and assembly.

Coupled Thermal Mechanical Model of the LORELEI Experimental Device with Multiple Interactions and Heat Sources during Controlled Transients and Accident Scenarios

Eran Landau*, Hadas Shanha**, Moran Ezra***, Niv Moran****, Avner Sasson*****

*Rotem Industries LTD., **Nuclear Research Center Negev, ***Rotem Industries LTD., ****Nuclear Research Center Negev, *****Rotem Industries LTD.

ABSTRACT

A primary component within the LORELEI experimental device designed for single-rod Loss of Coolant Accident (LOCA) experiments in the French JHR research reactor, is a double-wall pressure flask with unique geometry and loading conditions containing the fuel rod and a peripheral heater. During the experiment sequence, the fuel power is controlled by moving the entire systems position relative to the reactor core. Heat transfer between the fuel, a surrounding heater (and instrumentation holder) and the double-wall flask result in significant axial and azimuthal temperature variations over the flask walls. The resulting temperatures are also influenced by the gamma heating of the structure materials, and the Zirconium cladding exothermal oxidation reaction and ballooning during the transient. In Addition, the system is also subjected to several notable external loads and constraints. Design-by-analysis initially relied on separate heat transfer and temperature-displacement analysis (uncoupled). This method however, produced relatively large displacements resulting in significant contact between the inner and outer flask walls, which in turn should have a strong effect over the resulting temperature field. For this reason, a fully coupled thermal and mechanical model of the LORELEI experiment device is developed, using a transient ABAQUS/Implicit solver with several tailored user-subroutines. The model employs a "simplified" approach for heat transfer over a gap (Radiation and Conduction/Convection) between cylindrical bodies using controlled (programmed) interactions, to accurately enable transient heat transfer between the deformable surfaces. Volumetric heat generation (nuclear, gamma, oxidation) is computed in user-subroutine HETVAL for each material model using several solution dependent variables (SDV's), Common block parameters and spatial functions, defined in user-subroutines USDFLD and UAMP. The device velocity, position, and the heater power are controlled by two independent PID controllers using temperature sensors on the cladding and heater hot-spots. The fully-coupled simulation displays notable differences in the temperature variation over the flask walls, and helps examine the influence of the existing pre-loads, cladding ballooning, added design features (such as centering pins) and the desired controller functions. LORELEI design calculations and safety analysis are based on qualified models. At this stage in development, the model is employed in evaluating safety margins and possible optimization that would result from future qualification of the model. In this presentation, special challenges in the development of the model and important findings will be discussed. [1] L.Ferry, D.Parrat, C.Gonnier, C.Blandin, Y.Weiss, A.Sasson.
